Abstract

We consider the following Chern-Simons equation,

$$\Delta u + \frac{1}{\varepsilon^2} e^u (1 - e^u) = 4\pi \sum_{i=1}^N \delta_{p_i^{\varepsilon}}, \quad \text{in} \quad \Omega,$$
(0.1)

where Ω is a 2-dimensional flat torus, $\varepsilon > 0$ is a coupling parameter and δ_p stands for the Dirac measure concentrated at p. In this paper, we proved that the topological solutions of (0.1) are uniquely determined by the location of their vortices provided the coupling parameter ε is small and the collapsing velocity of vortices p_i^{ε} is slow enough or fast enough comparing with ε . This extends the uniqueness results of Choe [5] and Tarantello [22]. Meanwhile, for any topological solution ψ defined in \mathbb{R}^2 whose linearized operator is non-degenerate, we construct a sequence topological solutions u_{ε} of (0.1) whose asymptotic limit is exactly ψ after rescaling around 0. A consequence is that non-uniqueness of topological solutions in \mathbb{R}^2 implies non-uniqueness of topological solutions on torus with collapsing vortices.

1 Introduction

This paper is devoted to study the following semi-linear elliptic equation with exponential nonlinearity,

$$\Delta u + \frac{1}{\varepsilon^2} e^u (1 - e^u) = 4\pi \sum_{i=1}^N \delta_{p_i^{\varepsilon}}, \quad \text{in} \quad \Omega,$$
(1.1)

where Ω is a 2-dimensional flat torus, $\varepsilon > 0$ is a coupling parameter and δ_p stands for the Dirac measure concentrated at p. Through out the paper, we always normalize the volume of Ω as $|\Omega| = 1$.

(1.1) arises in the Abelian Chern-Simons model introduced by Jackiw-Weinberg [14] and Hong-Kim-Pac [13]. This model is given in the (2+1)-dimensional Minkowski space with metric $g_{\mu\nu} = diag(1, -1, -1)$. The Chern-Simons model in [13] and [14] can be formulated according to the Lagrangian density,

$$\mathcal{L} = \frac{\kappa}{4} \varepsilon^{\mu\nu\rho} F_{\mu\nu} A_{\rho} + D_{\mu} \phi \overline{D^{\mu}\phi} - \frac{1}{\kappa^2} |\phi|^2 (1 - |\phi|^2)^2$$
(1.2)

where A_{μ} ($\mu=0,1,2$) is a real gauge field on \mathbb{R}^3 , ϕ is the complex-valued Higgs field, $F_{\mu\nu}=\partial_{\mu}A_{\nu}-\partial_{\nu}A_{\mu}$ is the curvature tensor, $D_{\mu}=\partial_{\mu}-\sqrt{-1}A_{\mu}$ is the gauge covariant derivative, $\varepsilon^{\mu\nu\rho}$

^{*}genggenghuang@sjtu.edu.cn

[†]cslin@math.ntu.edu.tw

is totally skew symmetric tensor with $\varepsilon^{012} = 1$, and $\kappa > 0$ is the Chern-Simons coupling constant. When the energy for a pair (ϕ, A) is saturated, as in [14] and [13], one can get the following Bogomol'nyi type equation.

$$\begin{cases} (D_1 + iD_2)\phi = 0, \\ F_{12} + \frac{2}{\kappa} |\phi|^2 (|\phi|^2 - 1) = 0. \end{cases}$$
 (1.3)

As in Jaffe-Taubes [15], we let $u = \ln |\phi|^2$, and denote the zeros of ϕ by $\{p_1^{\varepsilon}, \dots, p_N^{\varepsilon}\}$, (1.3) can be transformed to (1.1) with $\varepsilon = \frac{\kappa}{2}$, if we impose the periodic boundary condition(introduced by 't Hooft [20]). For the details of derivation of (1.1) and related models, we refer the readers to Hong-Kim-Pac [13], Jackiw-Weinberg [14], Dunne [10], Tarantello [23] and Yang [24].

A sequence of solutions u_{ε} of (1.1) are called topological type if

$$u_{\varepsilon}(x) \to 0$$
, a.e. in Ω , as $\varepsilon \to 0$,

and called non-topological type if

$$u_{\varepsilon}(x) \to -\infty$$
, a.e. in Ω , as $\varepsilon \to 0$.

When the vortices don't change with ε , we rewrite (1.1) as

$$\Delta u + \frac{1}{\varepsilon^2} e^u (1 - e^u) = 4\pi \sum_{i=1}^N \delta_{p_i}, \quad \text{in} \quad \Omega.$$
 (1.4)

The construction of topological vortex condensate u(x) of (1.4) was first done by Caffarelli-Yang [2] via both monotone scheme and variational method. Then Tarantello [21] further exploited the variational structure and got both topological (for general N) and non-topological vortex condensates(for N=1). After that, many papers were devoted to find the non-topological vortex condensate for $N \geq 2$. For these developments, we refer readers to [6–9, 16–19] and references therein. All these works reveal that the non-topological solution isn't unique. As for the topological solutions, Choe [5] and Tarantello [22] independently proved that the topological solution of (1.4) is unique when the coupling constant $\varepsilon > 0$ is small enough. Their results can be summarized as follows.

Theorem A. There is a critical value of ε , say, $\varepsilon(p_1, \dots, p_N) > 0$ such that, for $0 < \varepsilon < \varepsilon(p_1, \dots, p_N)$, (1.4) admits a unique topological solution.

By Theorem A, we shall see that the critical value $\varepsilon(p_1,\cdots,p_N)$ doesn't only depend on the vortex number N but also on the location of the vortices on the flat torus Ω . For the physical applications, it is relevant to know to what extend the uniqueness property stated above depends on the smallness of the parameter ε , and hence on the location of the vortex points. In the end of the paper of Tarantello [22], the author considered a generalization of Theorem A, where the vortex points are allowed to vary with ε but no collapsing of vortices happens. So a natural question is whether the critical value $\varepsilon(p_1,\cdots,p_N)$ in Theorem A depends only on the vortex number N. We give a partial answer to this problem in this paper. First, we classify the points $\{p_1^{\varepsilon},\cdots,p_N^{\varepsilon}\}$ according to their asymptotic behavior. Along a subsequence, we define

$$A_{k,\varepsilon} = \{ p_i^{\varepsilon} | \lim_{\varepsilon \to 0} \frac{|p_i^{\varepsilon} - p_k^{\varepsilon}|}{\varepsilon} < +\infty \}.$$
 (1.5)

It follows directly from the definition of $A_{k,\varepsilon}$ that for any k,m, either $A_{k,\varepsilon}=A_{m,\varepsilon}$ or $A_{k,\varepsilon}\cap A_{m,\varepsilon}=\emptyset$. Without loss of generality, we can take $A_{i,\varepsilon}$, $i=1,\cdots,l$ such that

$$A_{i,\varepsilon} \cap A_{i,\varepsilon} = \emptyset, \quad i \neq j, \quad \bigcup_{i=1}^{l} A_{i,\varepsilon} = \{ p_1^{\varepsilon}, \cdots, p_N^{\varepsilon} \}.$$
 (1.6)

Theorem 1.1. There exists C(N) > 0 such that if for any set $A_{i,\varepsilon}$, $i = 1, \dots, l$ defined in (1.5), (1.6), either

(a.)
$$\lim_{\varepsilon \to 0} \frac{|p_k^{\varepsilon} - p_m^{\varepsilon}|}{\varepsilon} \ge C(N), \quad \text{for all different points} \quad p_k^{\varepsilon}, p_m^{\varepsilon} \in A_{i,\varepsilon}, \quad \text{or}$$
(b.)
$$\lim_{\varepsilon \to 0} \frac{|p_k^{\varepsilon} - p_m^{\varepsilon}|}{\varepsilon} \le \frac{1}{C(N)}, \quad \text{for all different points} \quad p_k^{\varepsilon}, p_m^{\varepsilon} \in A_{i,\varepsilon}$$
(1.7)

hold. Then equation (1.1) has a unique topological solution for all small $\varepsilon > 0$.

The constant C(N) in Theorem 1.1 is determined by the following theorem which is due to Choe [5].

Theorem B. [5] For any N > 0, there exists C(N) > 0, such that $\sum_{j=1}^{l} \alpha_j \leq N$ and given $\{p_1 \cdots, p_l\}$, either

(a.)
$$|p_i - p_j| \ge C(N)$$
, $\forall i \ne j$, or
(b.) $|p_i - p_j| \le \frac{1}{C(N)}$, $\forall i \ne j$. (1.8)

Then the equation

$$\Delta u + e^u (1 - e^u) = 4\pi \sum_{i=1}^l \alpha_i \delta_{p_i}, \quad in \quad \mathbb{R}^2,$$
(1.9)

has a unique topological solution. Moreover, the linearized operator

$$Lh = \Delta h + e^{u}(1 - 2e^{u})h \tag{1.10}$$

is an isomorphism from $H^2(\mathbb{R}^2)$ to $L^2(\mathbb{R}^2)$ satisfying

$$||Lh||_{L^2(\mathbb{R}^2)} \ge C||h||_{H^2(\mathbb{R}^2)}, \quad \forall h \in H^2(\mathbb{R}^2)$$
 (1.11)

for some constant C > 0.

Theorem B tells us that the restriction (1.7) in Theorem 1.1 is natural as we don't have the uniqueness of topological multivortex solutions of (1.9) in \mathbb{R}^2 . In the following, we will show, in some sense, the uniqueness of topological solutions of (1.1) is "equivalent" to the uniqueness of topological solutions of (1.9).

Theorem 1.2. Suppose ψ is a topological solution of (1.9) with its linearized operator L_{ψ} satisfying (1.11). Then there exists a topological solution u_{ε} solves

$$\Delta u_{\varepsilon} + \frac{1}{\varepsilon^2} e^{u_{\varepsilon}} (1 - e^{u_{\varepsilon}}) = 4\pi \sum_{i=1}^{l} \alpha_i \delta_{\varepsilon p_i}, \quad in \ \Omega,$$
(1.12)

and $\hat{u}_{\varepsilon}(x) = u_{\varepsilon}(\varepsilon x)$ such that

$$\|\hat{u}_{\varepsilon} - \psi\|_{L^{\infty}(B_{d/\varepsilon}(0))} \to 0$$
, for some constant $d > 0$ small. (1.13)

A direct consequence of Theorem 1.2 is the following corollary.

Corollary 1.1. Suppose, for some configuration $\{p_1, \dots, p_l\}$, there exist two different topological solutions u_1, u_2 of (1.9) with their linearized operators L_{u_1}, L_{u_2} satisfying (1.11). Then (1.12) possesses at least two topological solutions for small ε .

First, we sketch our proof for Theorem 1.1 and Theorem 1.2. Theorem 1.1 contains both existence and uniqueness. The existence part will follow from that there exists $\varepsilon_N > 0$ depending only on N such that if $0 < \varepsilon < \varepsilon_N$, (1.1) admits a maximal solution. We will revisit the construction of subsolutions in [2]. The uniqueness part of Theorem 1.1 is proved by contradiction. Suppose that there exist two sequences of distinct topological solutions $u_{1,\varepsilon}$, $u_{2,\varepsilon}$ of (1.1). Then there exists $x_{\varepsilon} \in \Omega$ such that

$$|u_{1,\varepsilon}(x_{\varepsilon}) - u_{2,\varepsilon}(x_{\varepsilon})| = |u_{1,\varepsilon} - u_{2,\varepsilon}|_{L^{\infty}(\Omega)} \neq 0,$$

and $x_{\varepsilon} \to p$ as $\varepsilon \to 0$ (up to a subsequence). Set

$$A_{\varepsilon} = \frac{u_{1,\varepsilon} - u_{2,\varepsilon}}{|u_{1,\varepsilon} - u_{2,\varepsilon}|_{L^{\infty}(\Omega)}}.$$
(1.14)

Then A_{ε} satisfies

$$\Delta A_{\varepsilon} + \frac{1}{\varepsilon^2} e^{\tilde{u}_{\varepsilon}} (1 - 2e^{\tilde{u}_{\varepsilon}}) A_{\varepsilon} = 0, \quad \text{in} \quad \Omega$$
 (1.15)

where \tilde{u}_{ε} is between $u_{1,\varepsilon}$ and $u_{2,\varepsilon}$. After a suitable scaling at x_{ε} , (1.15) converges to a bounded solution A of

$$\Delta A + e^{U}(1 - 2e^{U})A = 0$$
, in \mathbb{R}^{2} , (1.16)

where U is a topological solution of

$$\Delta U + e^{U}(1 - e^{U}) = 4\pi \sum_{i=1}^{l} \delta_{q_i}, \text{ in } \mathbb{R}^2.$$
 (1.17)

Here l and vortices $\{q_1, \dots, q_l\}$ are determined by the rescaling region and the collapsing velocity of the vortices compared with the coupling constant ε . Then we can apply Theorem B to get contradictions whenever $\{q_1, \dots, q_l\}$ satisfies the assumption (1.8).

The proof of Theorem 1.2 depends on the perturbation method which follows from Choe [5]. We consider topological solutions of (1.12) as a perturbation of $\psi_{\varepsilon}(x) = \psi(\frac{x}{\varepsilon})$. Set $u_{\varepsilon}(x) = \eta(x)\psi_{\varepsilon}(x) + \varepsilon^3 v_{\varepsilon}(x)$ and define an operator $G_{\varepsilon}(v) : H^2(\Omega) \to H^2(\Omega)$. We will prove G_{ε} is a well-defined contraction mapping in some suitable space \mathcal{B} .

This paper is organized as follows. In Section 2, we will collect some known results and establish some preliminary estimates for the topological solutions which are important to show the convergence of (1.15) to (1.16). In Section 3, we will prove Theorem 1.1 i.e. the existence and uniqueness of the topological solution. Section 4 is devoted to the construction of topological solutions which locally converge to a specified topological solution in \mathbb{R}^2 .

2 Preliminaries

Recall Green function G(x, y) on Ω ,

$$-\Delta_x G(x,y) = \delta_y - 1, \quad x, y \in \Omega, \quad \int_{\Omega} G(x,y) dx = 0.$$
 (2.1)

We list some properties of G(x, y) as follows:

- (a.) $\forall \phi \in C^2(\Omega), \ \phi(x) = \int_{\Omega} \phi(y) dy \int_{\Omega} G(x, y) \Delta \phi(y) dy$.
- (b.) $G(x,y) \in C^{\infty}(\Omega \times \Omega \setminus \{x=y\})$, $G(x,y) = -\frac{1}{2\pi} \ln|x-y| + \gamma(x,y)$ where $\gamma(x,y)$ is the regular part of G(x,y).
- (c.) $|G(x,y)| \leq C(1+|\ln|x-y||)$, and $G(x,y) \geq -C_0, \forall x,y \in \Omega$ and some constants $C,C_0>0$.

We refer the proof of the above properties to [1]. Also remind some facts due to Chan-Fu-Lin [3]. Consider

$$\Delta u + e^u (1 - e^u) = 0$$
, in \mathbb{R}^2 , $\int_{\mathbb{R}^2} e^u (1 - e^u) dx < \infty$. (2.2)

Applying the method of moving plane as in Chen-Li [4], after a translation, all the solutions of (2.2) are radially symmetric. Then consider

$$\begin{cases} u''(r;s) + \frac{1}{r}u'(r;s) + e^{u(r;s)}(1 - e^{u(r;s)}) = 0, & r > 0, \\ u(0;s) = s, \quad \beta(s) = \int_{\mathbb{R}^2} e^{u(r;s)}(1 - e^{u(r;s)})dx. \end{cases}$$
 (2.3)

By [3], $\beta(s)$ is a well-defined continuously differentiable function on $(-\infty,0)$. $\beta(s)$ is monotone increasing such that $\beta(s) \to +\infty$ as $s \to 0$, $\beta(s) \to 8\pi$ as $s \to -\infty$.

Before the proof of the existence and uniqueness of topological solutions of (1.1), we need to show the uniform lower bound of the coupling parameter ε which guarantees the existence of solutions of (1.1). In [2], the authors proved the following theorem.

Theorem C. [2] There is a critical value of ε , say, $\varepsilon(p_1, \dots, p_N) > 0$, satisfying,

$$\varepsilon(p_1,\cdots,p_N) \leq \frac{1}{\sqrt{16\pi N}}$$

such that, for $0 < \varepsilon \le \varepsilon(p_1, \dots, p_N)$, (1.4) has a solution, while for $\varepsilon > \varepsilon(p_1, \dots, p_N)$, the equation has no solution.

The proof of Theorem C is based on the construction of sub- and supersolutions. Since the existence of supersolutions always holds true, the delicate part is the construction of subsolution (Lemma 3 in [2]). However, if we revisit the construction of subsulctions as in Lemma 3 in [2], we will find $\varepsilon(p_1, \dots, p_N)$ is independent of the location of vortex. Although, the construction is similar, we present it here for the convenience of readers.

Theorem 2.1. There exists $\varepsilon(N) \geq N^{-cN}$ for some constant c > 0, such that, for any configuration $\{p_1, \dots, p_N\}$, (1.1) has a maximal solution provided $\varepsilon < \varepsilon(N)$.

Proof. The proof of Theorem 2.1 is also based on the monotone scheme. The only thing we need to take care of is the construction of subsolutions. Set

$$u_0(x) = -4\pi \sum_{i=1}^{N} G(x, p_i).$$

Then by property (c) of G(x,y), $u_0(x) \leq 4\pi C_0 N$. We want to construct a subsolution v,

$$\Delta v + \frac{1}{\epsilon^2} e^{v + u_0} (1 - e^{v + u_0}) \ge 4\pi N. \tag{2.4}$$

Define a smooth function $f_{\delta}(x)$ as follows:

$$f_{\delta}(x) = \begin{cases} 1; & \forall x \in \bigcup_{i=1}^{N} B_{\delta}(p_i); \\ 0, & \forall x \in \Omega \setminus \bigcup_{i=1}^{N} B_{2\delta}(p_i) \end{cases}$$

and $0 \le f_{\delta}(x) \le 1$ where δ is a parameter which will be determined later. By a direct computation, we get

$$C(\delta) = \int_{\Omega} 8\pi N f_{\delta} \le 32\pi^2 N^2 \delta^2.$$

Denote $g_{\delta}(x) = 8\pi N f_{\delta}(x) - C(\delta)$. Consider the following equation:

$$\Delta w = g_{\delta}, \quad \text{in} \quad \Omega, \quad \int_{\Omega} w dx = 0.$$
 (2.5)

Since $||g_{\delta}||_{L^{\infty}(\Omega)} \leq 8\pi N ||f_{\delta}||_{L^{\infty}(\Omega)} + C(\delta) \leq 8\pi N + 32\pi^2 N^2 \delta^2$, by standard $W^{2,p}$ estimates and Sobolev embedding, we get

$$||w||_{L^{\infty}(\Omega)} \le C||w||_{W^{2,2}(\Omega)} \le C||g_{\delta}||_{L^{2}(\Omega)} \le C(N + N^{2}\delta^{2}).$$
(2.6)

Hence we can choose $0 < C_1 \le 8\pi(C + C_0)(N + N^2\delta^2)$ such that

$$w_0 = w - C_1, \quad u_0 + w_0 \le -4\pi (C + C_0)(N + N^2 \delta^2) < \ln \frac{1}{2}.$$
 (2.7)

Let $\delta = \frac{1}{\sqrt{8\pi N}}$. Then $\forall x \in B_{\delta}(p_i)$, we have

$$\Delta w_0 = g_{\delta} \ge 4\pi N (2 - 8\pi N \delta^2)$$

$$\ge 4\pi N$$

$$\ge \frac{1}{\varepsilon^2} e^{u_0 + w_0} (e^{u_0 + w_0} - 1) + 4\pi N.$$
(2.8)

Set

$$\mu_0 = \inf\{e^{u_0 + w_0} | x \in \Omega \setminus \bigcup_{i=1}^N B_{\delta}(p_i)\}, \mu_1 = \sup\{e^{u_0 + w_0} | x \in \Omega \setminus \bigcup_{i=1}^N B_{\delta}(p_i)\}.$$

 $\mu_1 < \frac{1}{2}$ by (2.7). It remains to estimate μ_0 . By the choice of δ , we now have $w_0 \geq -C_2N$. By property (c) of G(x,y), we get

$$u_0(x) = -4\pi \sum_{i=1}^{N} G(x, p_i) \ge C_4 N(\ln \delta - 1) = -C_5 N(\ln N + 1), \quad \forall x \in \Omega \setminus \bigcup_{i=1}^{N} B_{\delta}(p_i).$$

The lower bound estimates of w_0 and u_0 imply that $\mu_0 \geq N^{-C_6N}$. So in order to show

$$\Delta w_0 = g_{\delta} \ge \frac{1}{\varepsilon^2} e^{u_0 + w_0} (e^{u_0 + w_0} - 1) + 4\pi N, \quad x \in \Omega \setminus \bigcup_{i=1}^N B_{\delta}(p_i), \tag{2.9}$$

we only need to guarantee $\frac{1}{\varepsilon^2}\mu_0 \geq 16\pi N$. This yields $\varepsilon \leq N^{-C_7N}$. This also implies w_0 is a subsolution of (2.4) for any configuration $\{p_1,\cdots,p_N\}$, $\forall 0<\varepsilon\leq N^{-C_7N}$. Then the arguments in [2] imply the existence of maximal solutions.

Lemma 2.1. Let u_{ε} be a sequence of solutions of (1.1). Then up to a subsequence, one of the following holds true:

- (i) $u_{\varepsilon} \to -\infty$, a.e. as $\varepsilon \to 0$.
- (ii) $u_{\varepsilon} \to 0$, a.e. as $\varepsilon \to 0$. Moreover, $u_{\varepsilon} \to 0$ in $L^p(\Omega)$, $\forall p \geq 1$.

Proof. Set $u_{0,\varepsilon}$ as

$$\Delta u_{0,\varepsilon} = 4\pi \sum_{i=1}^{N} \delta_{p_i^{\varepsilon}} - 4\pi N, \quad \int_{\Omega} u_{0,\varepsilon} dx = 0.$$

Let $d_{\varepsilon} = \int_{\Omega} u_{\varepsilon} dx$ and $u_{\varepsilon} = u_{0,\varepsilon} + w_{\varepsilon} + d_{\varepsilon}$. Then w_{ε} satisfies

$$\Delta w_{\varepsilon} + \frac{1}{\varepsilon^2} e^{u_{\varepsilon}} (1 - e^{u_{\varepsilon}}) = 4\pi N.$$

Claim: $\exists C_q > 0$ such that $\|\nabla w_{\varepsilon}\|_{L^q(\Omega)} \leq C_q$, $\forall q \in (1, 2)$. Let $q' = \frac{q}{q-1} > 2$. Then

$$\|\nabla w_{\varepsilon}\|_{L^{q}(\Omega)} \leq \sup\{\int_{\Omega} \nabla w_{\varepsilon} \nabla \varphi | \varphi \in W^{1,q'}(\Omega), \int_{\Omega} \varphi dx = 0, \|\nabla \varphi\|_{L^{q'}(\Omega)} \leq 1\}.$$

By Poincaré inequality and Sobolev embedding theorem, we see that

$$\|\varphi\|_{L^{\infty}(\Omega)} \le C(\|\varphi\|_{L^{q'}(\Omega)} + \|\nabla\varphi\|_{L^{q'}(\Omega)}) \le C\|\nabla\varphi\|_{L^{q'}(\Omega)}.$$

In view of the equation w_{ε} satisfying, one gets

$$\left| \int_{\Omega} \nabla w_{\varepsilon} \cdot \nabla \varphi dx \right| = \left| \int_{\Omega} \Delta w_{\varepsilon} \varphi dx \right| \le \|\varphi\|_{L^{\infty}(\Omega)} \left| \int_{\Omega} \frac{1}{\varepsilon^{2}} |e^{u_{\varepsilon}} (1 - e^{u_{\varepsilon}})| dx + 4\pi N \right| \le C$$

which implies $\|\nabla w_{\varepsilon}\|_{L^{q}(\Omega)} \leq C_{q}$. By Poincaré inequality, we also have

$$||w_{\varepsilon}||_{L^{q}(\Omega)} \leq C||\nabla w_{\varepsilon}||_{L^{q}(\Omega)}.$$

Therefore, up to a subsequence, there exists $w \in W^{1,q}(\Omega)$ and $\forall p \geq 1$ such that

$$w_{\varepsilon} \rightharpoonup w$$
 in $W^{1,q}(\Omega)$, $w_{\varepsilon} \rightarrow w$ in $L^p(\Omega)$, $w_{\varepsilon} \rightarrow w$ a.e..

It also follows from the definition of $u_{0,\varepsilon}$ that $u_{0,\varepsilon} \to u_0$ in $L^p(\Omega)$ for all $p \ge 1$. We consider the following two possible cases.

- 1. $\limsup_{\varepsilon \to 0} \frac{e^{d_{\varepsilon}}}{\varepsilon^2} \le C$ for some constant C.
- 2. $\limsup_{\varepsilon \to 0} \frac{e^{d\varepsilon}}{\varepsilon^2} = +\infty$.

If Case 1 happens, then

$$e^{u_{\varepsilon}} = e^{w_{\varepsilon} + u_{0,\varepsilon} + d_{\varepsilon}} < C \varepsilon^2 e^{w_{\varepsilon} + u_{0,\varepsilon}} \to 0$$

which implies $u_{\varepsilon} \to -\infty$ a.e..

Now we assume Case 2 happens. Since $u_{\varepsilon} < 0$ and $\int_{\Omega} u_{0,\varepsilon} dx = 0$, we see that $0 \le e^{d_{\varepsilon}} \le 1$. This means we can find $A \ge 0$ such that

$$\lim_{\varepsilon \to 0} \sup e^{d_{\varepsilon}} = A.$$

By Fatou's lemma, we get

$$4\pi N\varepsilon^2 e^{-d_{\varepsilon}} = \int_{\Omega} e^{w_{\varepsilon} + u_{0,\varepsilon}} (1 - e^{u_{\varepsilon}}) \ge \int_{\Omega} e^{w + u_{0}} (1 - Ae^{w + u_{0}}) dx.$$

Since $\int_{\Omega} w + u_0 dx = 0$, we get $A \equiv 1$. This ends the proof of Lemma 2.1.

Since our arguments always are along a subsequence, without loss of generality, in the arguments below, we always assume

$$P_n = \{p_1^{\varepsilon_n}, \dots, p_N^{\varepsilon_n}\} = \{p_{1,n}, \dots, p_{N,n}\} \to \{p_1, \dots, p_N\} = P,$$

 $u_n \to 0$ a.e. solves

$$\Delta u_n + \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) = 4\pi \sum_{i=1}^N \delta_{p_{i,n}}, \text{ in } \Omega.$$
 (2.10)

Set $d = \frac{1}{4}\inf_{p_i \neq p_j} |p_i - p_j|$. Then we have the following lemma.

Lemma 2.2. Suppose $u_n \to 0$ a.e. solves (2.10). Then for any $R_n \to +\infty$, $R_n \varepsilon_n \leq d$, we have

$$||u_n||_{L^{\infty}(\Omega\setminus\bigcup_{i=1}^N B_{R_n\varepsilon_n}(p_{i,n}))}\to 0.$$

Proof. First, we need to show for any compact set $K \subset \Omega \backslash P$,

$$||u_n||_{L^{\infty}(K)} \to 0.$$

Set $\delta = \frac{1}{4}d(K, P)$. Since $u_n < 0$ on Ω , we note that u_n is subharmonic in $B_{\delta}(x)$ for any $x \in K$. By using the mean value theorem and Lemma 2.1, we get

$$0 \le -u_n(x) \le \frac{1}{|B_{\delta}|} \|u_n\|_{L^1(\Omega)} \to 0$$
, as $n \to \infty$, $\forall x \in K$.

Next, we classify the points $\{p_{1,n}, \dots, p_{N,n}\}$ according to their asymptotic behavior. Define $A_{k,n}$ as

$$A_{k,n} = \{ p_{i,n} | \lim_{n \to \infty} \frac{|p_{i,n} - p_{k,n}|}{\varepsilon_n} < +\infty \}.$$

It's obvious that for any i, j, either $A_{i,n} = A_{j,n}$ or $A_{i,n} \cap A_{j,n} = \emptyset$ along a suitable subsequence. Without loss of generality, we can take $A_{i,n}$, $i = 1, \dots, l$ such that

$$A_{i,n} \cap A_{j,n} = \emptyset, \quad i \neq j, \quad \cup_{i=1}^{l} A_{i,n} = \{p_{1,n}, \cdots, p_{N,n}\}.$$

Set

$$r_n = \frac{1}{4} \min(\inf_{i \neq j} \frac{d(A_{i,n}, A_{j,n})}{\varepsilon_n}, R_n) \to +\infty.$$

So it's enough to prove that

$$||u_n||_{L^{\infty}(\Omega\setminus \bigcup_{i=1}^l B_{r_n\varepsilon_n}(q_{i,n}))} \to 0, \quad q_{i,n} \in A_{i,n}, \quad i=1,\cdots,l.$$

It follows from our choice that $\bigcup_{i=1}^{l} B_{r_n \varepsilon_n}(q_{i,n})$ covers the set $\{p_{1,n}, \cdots, p_{N,n}\}$ and $B_{r_n \varepsilon_n}(q_{i,n})$ $\cap B_{r_n \varepsilon_n}(q_{j,n}) = \emptyset$ for $i \neq j$. Hence, the set $B_d(0) \setminus \bigcup_{i=1}^{l} B_{r_n \varepsilon_n}(q_{i,n})$ is pathwise connected. Now suppose $u_n(x_n) \leq -c_0 < 0$, $x_n \in \Omega \setminus \bigcup_{i=1}^{l} B_{r_n \varepsilon_n}(q_{i,n})$. Then by our first step in the proof, without loss of generality, we may assume $x_n \to 0 \in P$. Choosing smooth curves $\gamma_n \subset B_d(0) \setminus \bigcup_{i=1}^{l} B_{r_n \varepsilon_n}(q_{i,n})$ joining x_n and $y_0 \in \partial B_d(0)$, by intermediate value theorem, we get $z_n \in \gamma_n$, $u_n(z_n) = s_0 < 0$ such that $\beta(s_0) > 4\pi N$ with $\beta(s)$ defined in (2.3) since it's already known $u_n(y_0) \to 0$. Set $\hat{u}_n(x) = u_n(\varepsilon_n x + z_n)$. Then $\hat{u}_n(x)$ solves

$$\begin{cases} \Delta \hat{u}_n + e^{\hat{u}_n} (1 - e^{\hat{u}_n}) = 0, & \text{in } B_{r_n/2}(0), \\ \hat{u}_n(x) < 0, \hat{u}_n(0) = s_0 < 0, \int_{B_{r_n/2}(0)} e^{\hat{u}_n} (1 - e^{\hat{u}_n}) \le 4\pi N. \end{cases}$$

As $\left|\frac{e^{\hat{u}_n}(1-e^{\hat{u}_n})}{\hat{u}_n}\right| \leq C$ uniformly, by Harnack inequality(Theorem 8.20 in [11]), we have \hat{u}_n is locally uniformly bounded. Applying standard $W^{2,p}$ and Schauder's estimates, one gets

$$\hat{u}_n \to \hat{u}$$
, in $C^2_{loc}(\mathbb{R}^2)$

and \hat{u} solves (2.2) with $\hat{u}(0) = s_0$. Then

$$4\pi N \ge \int_{\mathbb{P}^2} e^{\hat{u}} (1 - e^{\hat{u}}) dx \ge \beta(s_0) > 4\pi N.$$

This yields a contradiction and proves present lemma.

Lemma 2.3. Suppose u_n is a topological solution of (1.1). Then up to a subsequence, for any $R_n \to +\infty$, $R_n \varepsilon_n \leq d$, we have

$$\varepsilon_n^k |D^k u_n|_{L^{\infty}(\Omega \setminus \bigcup_{i=1}^N B_{R_n \varepsilon_n}(p_{i,n}))} \to 0,$$

for any $k \in \mathbb{N}$ and faster that any other power of $\frac{1}{R_n}$.

Proof. Set $\Omega_n = \Omega \setminus \bigcup_{i=1}^N B_{R_n \varepsilon_n}(p_{i,n}), \Omega'_n = \Omega \setminus \bigcup_{i=1}^N B_{2R_n \varepsilon_n}(p_{i,n}).$ By Lemma 2.2, we have

$$\int_{\Omega_{n}} |u_{n}| dx \leq (1 + |u_{n}|_{L^{\infty}(\Omega_{n})}) \int_{\Omega_{n}} \frac{|u_{n}|}{1 + |u_{n}|}
\leq (1 + |u_{n}|_{L^{\infty}(\Omega_{n})}) \int_{\Omega_{n}} (1 - e^{u_{n}})
\leq (1 + |u_{n}|_{L^{\infty}(\Omega_{n})}) e^{|u_{n}|_{L^{\infty}(\Omega_{n})}} \int_{\Omega_{n}} e^{u_{n}} (1 - e^{u_{n}}) \leq C\varepsilon_{n}^{2}.$$
(2.11)

In getting (2.11), we have used $|1-e^t| \ge \frac{|t|}{1+|t|}$, $\forall t \in \mathbb{R}$. Then for any $x \in \Omega'_n$, we note that u_n is subharmonic in $B_{R_n \varepsilon_n}(x)$. By mean value theorem and (2.11), we get

$$|u_n(x)| \le \frac{C}{R_n^2 \varepsilon_n^2} \int_{B_{R_n \varepsilon_n}(x)} |u_n(y)| dy \le \frac{C}{R_n^2}, \quad \forall x \in \Omega_n'.$$

Define $0 \le \varphi_n \in C^{\infty}(\Omega)$ such that

$$\varphi_n \equiv 0$$
, in $\bigcup_{i=1}^N B_{R_n \varepsilon_n}(p_{i,n})$, $\varphi \equiv 1$, in Ω'_n , $|D^k \varphi_n| \le C_k (R_n \varepsilon_n)^{-k}$, $k = 1, 2, \cdots$.

Then

$$\int_{\Omega_n'} \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) \le \frac{1}{\varepsilon_n^2} \int_{\Omega_n} e^{u_n} (1 - e^{u_n}) \varphi_n$$

$$= -\int_{\Omega} u_n \Delta \varphi_n dx \le \frac{C}{R_n^2 \varepsilon_n^2} \int_{\Omega_n} |u_n| \le \frac{C}{R_n^2}.$$
(2.12)

Repeating the procedure of (2.11) and (2.12), we have

$$\int_{\Omega_n} |u_n(x)| dx \le \frac{C_m \varepsilon_n^2}{R_n^{2m}}, \quad \int_{\Omega_n} \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) \le \frac{C_m}{R_n^{2m}}.$$

This implies

$$||u_n||_{L^{\infty}(\Omega_n)} \le \frac{C_m}{R_n^{2m}}, \quad ||\frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n})||_{L^{\infty}(\Omega_n)} \le \frac{C_m}{R_n^{2m} \varepsilon_n^2}.$$

Set $\hat{u}_n(x) = u_n(\varepsilon_n x)$. Then \hat{u}_n solves

$$\Delta \hat{u}_n + e^{\hat{u}_n} (1 - e^{\hat{u}_n}) = 0$$
, in $\frac{\Omega_n}{\varepsilon_n}$.

Since $|\hat{u}_n| \leq C_m/R_n^{2m}$ in Ω_n/ε_n , by standard $W^{2,p}$ -estimates and Schauder estimates, we get

$$|D^k \hat{u}_n|_{L^{\infty}(\Omega_n/\varepsilon_n)} \le \frac{C_{k,m}}{R^{2m}}, \quad \forall k \ge 0.$$

Scaling back to $u_n(x)$, one get

$$|D^k u_n|_{L^{\infty}(\Omega \setminus \bigcup_{i=1}^N B_{R_n \varepsilon_n}(p_{i,n}))} \le \frac{C_m}{R_n^{2m} \varepsilon_n^k}$$

If no confuse occurs, in the remaining part of this paper, $A_{k,n}$, $q_{k,n}$, $k=1,\cdots,l$, r_n always mean the terminologies defined in Lemma 2.2. Suppose $p_{1,n},\cdots,p_{l_1,1,n}\in A_{1,n},l_{1,1}$ is the number of elements in $A_{1,n}$ and $p_{1,n}=0$ after a shift of coordinates. Then set $v_n=u_n(x)-2\sum_{i=1}^{l_{1,1}}\ln|x-p_{i,n}|$. We have the following important a priori estimates.

Lemma 2.4. Suppose u_n is a topological solution of (2.10). Then

$$\frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) \to 4\pi \sum_{i \in I} l_i \delta_{p_i},$$

weakly in the sense of measure in Ω , where $I \subset \{1, \dots, N\}$ is a set of indices identifying all distinct vortices in $\{p_1, \dots, p_N\}$, $l_i \in \mathbb{N}$ is the multiplicity of p_i , $i \in I$. And for any $\tilde{r}_n \leq r_n$, $\tilde{r}_n \to +\infty$, we have

$$\int_{B_{\tilde{r}_n \varepsilon_n}(0)} \frac{1}{\varepsilon_n^2} (1 - e^{u_n})^2 = 4\pi l_{1,1}^2 + 4\pi \sum_{i=1}^{l_{1,1}} p_{i,n} \cdot \nabla v_n(p_{i,n}) + o(1), \int_{\Omega \setminus \bigcup_{i=1}^l B_{\tilde{r}_n \varepsilon_n}(q_{i,n})} \frac{1}{\varepsilon_n^2} (1 - e^{u_n})^2 = o(1).$$

Proof. The first part is easy. Since for any $\varphi \in C^{\infty}(\Omega)$, we have

$$\begin{split} &\left|\frac{1}{\varepsilon_n^2}\int_{\Omega}e^{u_n}(1-e^{u_n})\varphi-4\pi\sum_{i=1}^N\varphi(p_{i,n})\right| = \left|-\int_{\Omega}\Delta u_n\varphi\right| = \left|-\int_{\Omega}\Delta\varphi u_n\right| \\ &\leq \|\Delta\varphi\|_{L^{\infty}(\Omega)}\|u_n\|_{L^1(\Omega)}\to 0, \quad \text{as} \quad \varepsilon_n\to 0 \end{split}$$

and this proves the first part if we notice $P_n \to P$.

Denote $f_n = 2\sum_{i=1}^{l_{1,1}} \ln|x - p_{i,n}|$. And v_n solves

$$\Delta v_n + \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) = 0, \quad \text{in} \quad B_{\tilde{r}_n \varepsilon_n}(0).$$
 (2.13)

By Lemma 2.3 and the property of $p_{i,n}$, $i = 1, \dots, l_{1,1}$, we have

$$|\nabla v_n + \frac{2l_{1,1}\nu}{\tilde{r}_n \varepsilon_n}| = O(\frac{1}{\tilde{r}_n^2 \varepsilon_n}), \quad \text{on} \quad \partial B_{\tilde{r}_n \varepsilon_n}(0)$$
(2.14)

where ν is the outward normal of $\partial B_{\tilde{r}_n \varepsilon_n}(0)$. In view of

$$\int_{B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nabla v_n) \Delta v_n = \int_{\partial B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nabla v_n) (\nabla v_n \cdot \nu) - \frac{1}{2} \int_{\partial B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nu) |\nabla v_n|^2
= \frac{1}{2} \int_{\partial B_{\tilde{r}_n \varepsilon_n}(0)} \left(O\left(\frac{1}{\tilde{r}_n}\right) - 2l_{1,1} \right) \left(O\left(\frac{1}{\tilde{r}_n^2 \varepsilon_n}\right) - \frac{2l_{1,1}}{\tilde{r}_n \varepsilon_n} \right)
= 4\pi l_{1,1}^2 + O\left(\frac{1}{\tilde{r}_n}\right).$$
(2.15)

And

$$\int_{B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nabla v_n) \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n})$$

$$= \int_{B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nabla u_n) \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) - (x \cdot \nabla f_n) (-\Delta v_n)$$

$$= \int_{B_{\tilde{r}_n \varepsilon_n}(0)} \frac{1}{\varepsilon_n^2} (1 - e^{u_n})^2 - \frac{1}{2\varepsilon_n^2} \int_{\partial B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nu) (1 - e^{u_n})^2 + \int_{B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nabla f_n) \Delta v_n.$$
(2.16)

And

$$\int_{B_{\tilde{r}_n \varepsilon_n}(0)} (x \cdot \nabla f_n) \Delta v_n$$

$$= -8\pi l_{1,1}^{2} + 2\lim_{\delta \to 0} \sum_{i=1}^{l_{1,1}} \int_{B_{\tilde{r}_{n}\varepsilon_{n}}(0)\backslash B_{\delta}(p_{i,n})} \nabla \cdot [p_{i,n} \cdot (\ln|x - p_{i,n}| - \ln(\tilde{r}_{n}\varepsilon_{n}))] \Delta v_{n} + o(1)$$

$$= -8\pi l_{1,1}^{2} - 4\pi \sum_{i=1}^{l_{1,1}} p_{i,n} \cdot \nabla v_{n}(p_{i,n}) + 2\pi \sum_{i=1}^{l_{1,1}} \int_{\partial B_{\tilde{r}_{n}\varepsilon_{n}}(0)} (p_{i,n} \cdot \nu) (\ln|x - p_{i,n}| - \ln(\tilde{r}_{n}\varepsilon_{n})) \Delta v_{n}$$

$$-2\pi \sum_{i=1}^{l_{1,1}} \int_{\partial B_{\tilde{r}_{n}\varepsilon_{n}}(0)} \nabla (p_{i,n} \cdot \nabla v_{n}) \cdot \nu (\ln|x - p_{i,n}| - \ln(\tilde{r}_{n}\varepsilon_{n})) + o(1)$$

$$= -8\pi l_{1,1}^{2} - 4\pi \sum_{i=1}^{l_{1,1}} p_{i,n} \cdot \nabla v_{n}(p_{i,n}) + o(1).$$

$$(2.17)$$

In order to get (2.15)-(2.17), we have used the estimates in Lemma 2.3 and $\ln |x-p_{in}| - \ln(\tilde{r}_n \varepsilon_n) \to 0$ on $\partial B_{\tilde{r}_n \varepsilon_n}(0)$. Combining (2.15)-(2.17), we get

$$\frac{1}{\varepsilon_n^2} \int_{B_{\tilde{r}_n \varepsilon_n}(0)} (1 - e^{u_n})^2 = 4\pi l_{1,1}^2 + 4\pi \sum_{i=1}^{l_{1,1}} p_{i,n} \cdot \nabla v_n(p_{i,n}) + o(1).$$
 (2.18)

Now we want to show $p_{i,n} \cdot \nabla v_n(p_{i,n})$ is uniformly bounded for $i = 1, \dots, l_{1,1}$. By Green's representation formula, one gets

$$u_n - u_{0,n} = \int_{\Omega} u_n(y) dy + \int_{\Omega} G(x, y) \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) dy.$$
 (2.19)

Since $G(x,y) = -\frac{1}{2\pi} \ln|x-y| + \gamma(x,y)$ where $\gamma(x,y)$ is the regular part, one can expect that for $x \in B_{R\varepsilon_n}(0)$ for some fixed R large enough,

$$|\nabla u_{n} - 2\sum_{i=1}^{l_{1,1}} \frac{x - p_{i,n}}{|x - p_{i,n}|^{2}}|$$

$$\leq C + \int_{\Omega} \frac{1}{|x - y|} \frac{1}{\varepsilon_{n}^{2}} e^{u_{n}} (1 - e^{u_{n}}) dy + 2\sum_{i=l_{1,1}+1}^{l_{1}} \frac{x - p_{i,n}}{|x - p_{i,n}|^{2}}$$

$$\leq C + \int_{B_{\varepsilon_{n}}(x)} \frac{1}{|x - y|} \frac{1}{\varepsilon_{n}^{2}} e^{u_{n}} (1 - e^{u_{n}}) dy + \int_{\Omega \setminus B_{\varepsilon_{n}}(x)} \frac{1}{|x - y|} \frac{1}{\varepsilon_{n}^{2}} e^{u_{n}} (1 - e^{u_{n}}) dy + o\left(\frac{1}{\varepsilon_{n}}\right)$$

$$\leq C + \frac{C}{\varepsilon_{n}}.$$
(2.20)

By (2.20) and the uniform bound of $\frac{|p_{i,n}|}{\varepsilon_n}$, $i=1,\dots,l_{1,1}$, we can get $p_{i,n}\cdot\nabla v_n(p_{i,n})$ is uniformly bounded for $i=1,\dots,l_{1,1}$.

From $\left|\frac{1}{\varepsilon_n^2}e^{u_n}(1-e^{u_n})\right|_{L^1(\Omega)}=4\pi N$ and $u_n<0$, we see that for $\Omega_n=\Omega\setminus\bigcup_{i=1}^l B_{\tilde{r}_n\varepsilon_n}(q_{i,n})$

$$\frac{1}{\varepsilon_n^2} \int_{\Omega_n} (1 - e^{u_n})^2 \le \sup_{\Omega_n} (1 - e^{u_n}) \inf_{\Omega_n} e^{u_n} \int_{\Omega_n} \frac{1}{\varepsilon_n^2} e^{u_n} (1 - e^{u_n}) \to 0.$$

Denote

$$\hat{u}_n(x) = u_n(\varepsilon_n x), \quad \frac{p_{i,n}}{\varepsilon_n} \to \hat{p}_i, \quad i = 1, \dots, l_{1,1}.$$

Lemma 2.5. Suppose $\hat{u}(x)$ is the unique topological solution of

$$\begin{cases} \Delta \hat{u} + e^{\hat{u}} (1 - e^{\hat{u}}) = 4\pi \sum_{i=1}^{l_{1,1}} \delta_{\hat{p}_i}, & in \quad \mathbb{R}^2, \\ \hat{u} < 0, \sup_{\mathbb{R}^2 \setminus \bigcup_{i=1}^{l_{1,1}} B_1(\hat{p}_i)} |\nabla \hat{u}| < +\infty, \quad \int_{\mathbb{R}^2} (1 - e^{\hat{u}}) dx < +\infty \end{cases}$$

where \hat{p}_i satisfies the assumptions in Theorem B. Set

$$\hat{v}_n(x) = \hat{u}_n(x) - \sum_{i=1}^{l_{1,1}} \ln \frac{|x - \frac{p_{i,n}}{\varepsilon_n}|^2}{1 + |x - \frac{p_{i,n}}{\varepsilon_n}|^2} = \hat{u}_n - h_n, \quad \hat{v}(x) = \hat{u}(x) - \sum_{i=1}^{l_{1,1}} \ln \frac{|x - \hat{p}_i|^2}{1 + |x - \hat{p}_i|^2} = \hat{u} - h.$$

Then $\lim_{\varepsilon \to 0} \sup_{B_{r_n}(0)} |\hat{v}_n - \hat{v}| = 0.$

Proof. Claim: $\sup_{B_{r_n}(0)\setminus \bigcup_{i=1}^{l_{1,1}} B_1(\hat{p}_i)} |\hat{u}_n| \leq C.$

Suppose the claim isn't true. We can pick up $z_n \in B_{r_n}(0) \setminus \bigcup_{i=1}^{l_{1,1}} B_1(\hat{p}_i)$ such that $\hat{u}_n(z_n) \to -\infty$. By Lemma 2.3, z_n must be uniformly bounded. Otherwise, one can define $\tilde{r}_n = \frac{|z_n|}{4} \to +\infty$ and $\Omega_n = \Omega \setminus \bigcup_{i=1}^{l} B_{\tilde{r}_n \varepsilon_n}(q_{i,n})$. Then Lemma 2.3 tells us that $||u_n||_{L^{\infty}(\Omega_n)} \to 0$ which contradicts to $u_n(z_n \varepsilon_n) = \hat{u}_n(z_n) \to -\infty$ as $z_n \varepsilon_n \in \Omega_n$. Because \hat{u}_n solves

$$\Delta \hat{u}_n + e^{\hat{u}_n} (1 - e^{\hat{u}_n}) = 0$$
, in $B_{r_n}(0) \setminus \bigcup_{i=1}^{l_{1,1}} B_1(\hat{p}_i)$, $\hat{u}_n < 0$

and $\left|\frac{e^{\hat{u}_n}(1-e^{\hat{u}_n})}{\hat{u}_n}\right| \in L^{\infty}$, by Harnack inequality, we have

 $\hat{u}_n \to -\infty$, locally in any compact set $K \subset B_{r_n}(0) \setminus \bigcup_{i=1}^{l_{1,1}} B_1(\hat{p}_i)$.

This implies that

$$\int_{B_R(0)} (1 - e^{\hat{u}_n})^2 \ge \frac{1}{4} \pi R^2 \to +\infty, \text{ as } R \to +\infty$$

which contradicts to

$$\int_{B_R(0)} (1 - e^{\hat{u}_n})^2 \le \frac{1}{\varepsilon_n^2} \int_{B_{r_n \varepsilon_n}(0)} (1 - e^{u_n})^2 \le C.$$

This proves our claim. Since \hat{v}_n solves

$$\Delta \hat{v}_n + e^{\hat{u}_n} (1 - e^{\hat{u}_n}) = \sum_{i=1}^{l_{1,1}} \frac{4}{(1 + |x - \frac{p_{i,n}}{\varepsilon_n}|^2)^2} = g_n, \quad \text{in} \quad B_{r_n}(0).$$

By the claim, we have

$$\|\hat{v}_n\|_{L^{\infty}(\partial B_R)} \le C_R$$
, for $R \ge \max_{1 \le i \le l_{1,1}} |\hat{p}_i| + 1$.

Applying maximum principle to $\Delta \hat{v}_n \pm (4l_{1,1}+1) \geq 0$, one gets $\|\hat{v}_n\|_{L^{\infty}(B_R)} \leq C_R$. From the standard $W^{2,p}$ estimates, we have $\hat{v}_n \to \hat{v}$ in $W^{2,p}_{loc}(\mathbb{R}^2)$ for p>1. By Sobolev embedding theorem, we have $\nabla \hat{v}_n(\frac{p_{i,n}}{\hat{v}_n}) \to \nabla \hat{v}(\hat{p}_i)$. This implies

$$\int_{B_{r_n}(0)} (1 - e^{\hat{u}_n})^2 = 4\pi l_{1,1}^2 + 4\pi \sum_{i=1}^{l_{1,1}} \hat{p}_i \cdot \nabla \hat{v}(\hat{p}_i) + o(1).$$

Then by Fatou's Lemma

$$\int_{B_{r_n}(0)} (e^{\hat{u}_n} - e^{\hat{u}})^2 = \int_{B_{r_n}(0)} (e^{\hat{u}_n} - 1)^2 + (e^{\hat{u}} - 1)^2 - 2 \int_{B_{r_n}(0)} (1 - e^{\hat{u}_n}) (1 - e^{\hat{u}}) \le o(1).$$

This again implies

$$o(1) = \int_{B_{r_n}(0) \backslash B_R(0)} (e^{\hat{u}_n} - e^{\hat{u}})^2 \ge \min_{B_{r_n}(0) \backslash B_R(0)} (e^{2\hat{u}_n}, e^{2\hat{u}}) \int_{B_{r_n}(0) \backslash B_R(0)} (\hat{u}_n - \hat{u})^2,$$

or $\int_{B_{r_n}(0)\backslash B_R(0)} (\hat{u}_n - \hat{u})^2 = o(1)$. Direct computation yields that

$$|h_n - h|_{L^2(B_{r_n}(0) \setminus B_R(0))} + |g_n - g|_{L^2(B_{r_n}(0))} = o(1), \text{ as } n \to \infty.$$

By the local convergence of $\hat{v}_n \to \hat{v}$ and standard $W^{2,p}$ estimates, we have

$$\lim_{\varepsilon_n \to 0} \sup_{B_{r_n}(0)} |\hat{v}_n - \hat{v}| \to 0.$$

3 The existence and uniqueness of topological solutions

Proof of Theorem 1.1. By Theorem 2.1, for any configuration $\{p_1, \cdots, p_N\}$, $\exists \varepsilon_N > 0$, $\forall 0 < \varepsilon \leq \varepsilon_N$, (1.4) admits a maximal solution. Suppose u_n is a sequence of maximal solutions of (1.1) with configuration $\{p_{1,n}, \cdots, p_{N,n}\}$ and coupling parameter $\varepsilon_n \to 0$. By Lemma 2.1, we have either $u_n \to 0$ a.e. or $u_n \to -\infty$ a.e.. Set $v_n = u_n - u_{0,n}$. Since w_0 constructed in Theorem 2.1 is a subsolution of

$$\Delta v_n + \frac{1}{\varepsilon_n^2} e^{v_n + u_{0,n}} (1 - e^{v_n + u_{0,n}}) = 4\pi N,$$

by the monotone decreasing property of maximal solutions with respect to ε , we have $v_n \geq w_0$ which is uniformly bounded from below. This implies $u_n = v_n + u_{0,n} \to 0$ a.e. and proves the existence part.

Now suppose there are two different topological solutions of (1.1) $u_{1,n}$, $u_{2,n}$. Set

$$\phi_n(x) = \frac{(u_{1,n} - u_{2,n})(x)}{|u_{1,n} - u_{2,n}|_{L^{\infty}(\Omega)}}, \quad |\phi_n(x_n)| = ||\phi_n||_{L^{\infty}(\Omega)} = 1.$$

We consider the following two cases.

(I)
$$\tilde{r}_n = \frac{1}{4} \min(\frac{|x_n - p_{1,n}|}{\varepsilon_n}, \cdots, \frac{|x_n - p_{N,n}|}{\varepsilon_n}) \to +\infty$$
. By Lemma 2.3, one has

$$||u_{1,n}||_{L^{\infty}(B_{\tilde{r}_n \varepsilon_n}(x_n))}, ||u_{2,n}||_{L^{\infty}(B_{\tilde{r}_n \varepsilon_n}(x_n))} \to 0.$$

Set $\hat{\phi}_n(x) = \phi_n(\varepsilon_n x + x_n)$, $\hat{u}_{i,n}(x) = u_{i,n}(\varepsilon_n x + x_n)$, i = 1, 2. Then $\hat{\phi}_n$ satisfies

$$\Delta \hat{\phi}_n + e^{\hat{u}_n} (1 - 2e^{\hat{u}_n}) \hat{\phi}_n = 0, \text{ in } B_{\tilde{r}_n}(0),$$
 (3.1)

where \hat{u}_n is between $\hat{u}_{1,n}$, $\hat{u}_{2,n}$. From standard $W^{2,p}$ estimates and Schauder's estimates, we obtain a subsequence $\hat{\phi}_n \to \hat{\phi}$ in $C^2_{loc}(\mathbb{R}^2)$ with $\hat{\phi}$ satisfying

$$\Delta \hat{\phi} - \hat{\phi} = 0$$
, in \mathbb{R}^2 ,
 $|\hat{\phi}(0)| = ||\hat{\phi}||_{L^{\infty}} = 1$.

(II) $\tilde{r}_n \leq C < +\infty$. Without loss of generality, we may assume $p_{1,n} = 0$ and $\frac{|x_n|}{\varepsilon_n} \leq C$. Set $\hat{\phi}_n(x) = \phi_n(\varepsilon_n x + x_n)$. Then as in Case (I), by Lemma 2.5 and Theorem B, we obtain a subsequence $\hat{\phi}_n \to \hat{\phi}$ in $C^2_{loc}(\mathbb{R}^2)$ with $\hat{\phi}$ satisfying

$$\Delta \hat{\phi} + e^{\hat{u}} (1 - 2e^{\hat{u}}) \hat{\phi} = 0, \text{ in } \mathbb{R}^2,$$

 $|\hat{\phi}(0)| = ||\hat{\phi}||_{L^{\infty}} = 1.$

Here \hat{u} is the unique topological solution of

$$\begin{cases} \Delta \hat{u} + e^{\hat{u}} (1 - e^{\hat{u}}) = 4\pi \sum_{i=1}^{l_{1,1}} \delta_{\hat{p}_i}, & \text{in} \quad \mathbb{R}^2, \\ \int_{\mathbb{R}^2} (1 - e^{\hat{u}})^2 < \infty, & \hat{u} < 0. \end{cases}$$

In order to obtain contradiction, we need to show $\hat{\phi} \in H^2(\mathbb{R}^2)$ both in Case (I) and (II). Let $\eta(x) \in C_c^{\infty}(\mathbb{R}^2)$, $\eta \equiv 1$ in $B_1(0)$, $\eta \equiv 0$ in $B_2^c(0)$, $\eta_R(x) = \eta(\frac{x}{R})$. Taking $\eta_R^2 \hat{\phi}$ as a test function, we get

$$\int_{\mathbb{R}^2} \eta_R^2 |\nabla \hat{\phi}|^2 + e^{2\hat{u}} \eta_R^2 \hat{\phi}^2 \leq \frac{1}{2} \int_{\mathbb{R}^2} \eta_R^2 |\nabla \hat{\phi}|^2 + \frac{C}{R^2} \int_{B_{2R} \backslash B_R} \hat{\phi}^2 + \int_{\mathbb{R}^2} e^{\hat{u}} (1 - e^{\hat{u}}) \eta_R^2 \hat{\phi}^2 \leq C.$$

This implies $\hat{\phi} \in H^1(\mathbb{R}^2)$. Taking $\eta_R^2 \Delta \hat{\phi}$ as a test function, one gets,

$$\int_{\mathbb{R}^{2}} \eta_{R}^{2} |D_{ij}\hat{\phi}|^{2} = \int_{\mathbb{R}^{2}} 2\eta_{R} D_{i} \eta_{R} D_{i} \hat{\phi} D_{jj} \hat{\phi} - \int_{\mathbb{R}^{2}} 2\eta_{R} D_{j} \eta_{R} D_{i} \hat{\phi} D_{ij} \hat{\phi} + \int_{\mathbb{R}^{2}} e^{\hat{u}} (1 - 2e^{\hat{u}}) \eta_{R}^{2} \hat{\phi} \Delta \hat{\phi}
\leq \frac{1}{2} \int_{\mathbb{R}^{2}} \eta_{R}^{2} |D_{ij}\hat{\phi}|^{2} + C \leq 2C.$$

Now we have $\hat{\phi} \in H^2(\mathbb{R}^2)$, by Theorem B, $\hat{\phi} \equiv 0$ which contradicts to $|\hat{\phi}(0)| = 1$.

4 Construction of topological solutions

Suppose $\psi(x)$ is a topological solution of

$$\Delta \psi + e^{\psi} (1 - e^{\psi}) = 4\pi \sum_{i=1}^{l} \alpha_i \delta_{p_i}, \quad \text{in} \quad \mathbb{R}^2.$$
 (4.1)

The corresponding linearized operator L is $\Delta + e^{\psi}(1 - 2e^{\psi})$ and we assume that

$$||Lh||_{L^2(\mathbb{R}^2)} \ge C||h||_{H^2(\mathbb{R}^2)}, \quad \forall h \in H^2(\mathbb{R}^2) \quad \text{for some constant } C > 0.$$
 (4.2)

Also by Han [12], for $R > \max |p_i| + 1$, we have

$$|\psi(x)| + |\nabla \psi(x)| \le c_1 e^{-c_2|x|}, \quad \forall |x| \ge R, \quad \text{for some constants } c_1, c_2 > 0. \tag{4.3}$$

Consider a cut-off function $\eta(x)$ with $\eta(x) \equiv 1$ in $B_{\delta}(0)$, $\eta(x) \equiv 0$ in $B_{2\delta}^{c}(0)$ for some $\delta > 0$ small and $F_{\varepsilon}(v)$ as follows

$$F_{\varepsilon}(v) = \Delta v + \frac{1}{\varepsilon^{5}} e^{\eta \psi_{\varepsilon} + \varepsilon^{3} v} (1 - e^{\eta \psi_{\varepsilon} + \varepsilon^{3} v}) - \frac{\eta}{\varepsilon^{5}} e^{\psi_{\varepsilon}} (1 - e^{\psi_{\varepsilon}}) + \varepsilon^{-3} (2\nabla \eta \cdot \nabla \psi_{\varepsilon} + \psi_{\varepsilon} \Delta \eta), \tag{4.4}$$

where $\psi_{\varepsilon}(x) = \psi(\frac{x}{\varepsilon})$. By a direct computation, it can be checked that $u_{\varepsilon} = \eta \psi_{\varepsilon} + \varepsilon^3 v_{\varepsilon}$ is a solution of

$$\Delta u_{\varepsilon} + \frac{1}{\varepsilon^2} e^{u_{\varepsilon}} (1 - e^{u_{\varepsilon}}) = 4\pi \sum_{i=1}^{l} \alpha_i \delta_{\varepsilon p_i}, \quad \text{in} \quad \Omega$$
 (4.5)

provided $F_{\varepsilon}(v_{\varepsilon}) = 0$ and ε is small enough.

Lemma 4.1. There is a constant $\varepsilon_0 > 0$ such that if $0 < \varepsilon < \varepsilon_0$, we have

- (I) $||F_{\varepsilon}(0)||_{L^{2}(\Omega)} \leq c_{1}e^{-c_{2}/\varepsilon}$ for some constants $c_{1}, c_{2} > 0$.
- (II) $DF_{\varepsilon}(0)$ is an isomorphism from $H^{2}(\Omega)$ onto $L^{2}(\Omega)$, moreover, we have

$$||DF_{\varepsilon}(0)h||_{L^{2}(\Omega)} \geq C||h||_{H^{2}(\Omega)}, \quad \forall h \in H^{2}(\Omega) \quad \text{for some constant } C > 0.$$

(III)
$$||DF_{\varepsilon}(v)h - DF_{\varepsilon}(0)h||_{L^{2}(\Omega)} \leq C\varepsilon ||h||_{H^{2}(\Omega)}$$
, for $||v||_{H^{2}(\Omega)} \leq 1$, $\forall h \in H^{2}(\Omega)$.

Proof. By definition of $F_{\varepsilon}(v)$, we have

$$F_{\varepsilon}(0) = \frac{1}{\varepsilon^{5}} (e^{\eta \psi_{\varepsilon}} (1 - e^{\eta \psi_{\varepsilon}}) - \eta e^{\psi_{\varepsilon}} (1 - e^{\psi_{\varepsilon}})) + \frac{1}{\varepsilon^{3}} (2\nabla \eta \cdot \nabla \psi_{\varepsilon} + \psi_{\varepsilon} \Delta \eta).$$

Since the support of $\nabla \eta$, $\Delta \eta$ is contained in $B_{2\delta}(0) \backslash B_{\delta}(0)$ and $\psi_{\varepsilon}(x)$, $\nabla \psi_{\varepsilon}$ decay to 0 exponentially fast as $e^{-c/\varepsilon}$ for $|x| \geq \delta$ by (4.3), we have

$$\left| \frac{1}{\varepsilon^3} (2\nabla \eta \cdot \nabla \psi_{\varepsilon} + \psi_{\varepsilon} \Delta \eta) \right| \le c_1 e^{-c_2/\varepsilon}.$$

Since $\eta \equiv 1$ in $B_{\delta}(0)$, the first term of $F_{\varepsilon}(0)$ vanishes in $B_{\delta}(0)$ and again by the exponential decay property of ψ_{ε} in $|x| \geq \delta$, one get $||F_{\varepsilon}(0)||_{L^{\infty}(\Omega)} \leq c_1 e^{-c_2/\varepsilon}$ which implies (I) is true.

We prove (II) by contradiction. Suppose there exists $h_n \in H^2(\Omega)$ such that

$$||h_n||_{H^2(\Omega)} = 1, \quad ||DF_{\varepsilon_n}(0)h_n||_{L^2(\Omega)} = o(1).$$

Set $\eta_1(x) = \eta(4x)$ and $\tilde{h}_n = (1 - \eta_1)h_n$. Then \tilde{h}_n solves

$$\Delta \tilde{h}_n - \frac{1}{\varepsilon_n^2} e^{\eta \psi_{\varepsilon}} (2e^{\eta \psi_{\varepsilon}} - 1) \tilde{h}_n = (1 - \eta_1) DF_{\varepsilon_n}(0) h_n - 2\nabla \eta_1 \cdot \nabla h_n - \Delta \eta_1 h_n. \tag{4.6}$$

Multiplying (4.6) with \tilde{h}_n and integrating by parts, we get

$$\|\nabla \tilde{h}_n\|_{L^2(\Omega)}^2 + \frac{1}{\varepsilon_n^2} \|\tilde{h}_n\|_{L^2(\Omega)}^2 \le C \|\tilde{h}_n\|_{L^2(\Omega)} (\|h_n\|_{H^1(B_{\delta/4}^c(0))} + \|DF_{\varepsilon_n}(0)h_n\|_{L^2(B_{\delta/4}^c(0))})$$
(4.7)

for some constant C > 0. From (4.7) and $||h_n||_{H^1(\Omega)} \le 1$, one has $||\tilde{h}_n||_{L^2(\Omega)} \le C\varepsilon_n^2$. Since $\eta_1 \equiv 1$ in $B_{\delta/2}^c(0)$, (4.7) implies

$$\|\nabla h_n\|_{L^2(B_{\delta/2}^c(0))} + \frac{1}{\varepsilon_n} \|h_n\|_{L^2(B_{\delta/2}^c(0))} \le \|\nabla \tilde{h}_n\|_{L^2(\Omega)} + \frac{1}{\varepsilon_n} \|\tilde{h}_n\|_{L^2(\Omega)} \le C\varepsilon_n. \tag{4.8}$$

Let $\eta_2(x) = \eta(2x)$ and $\bar{h}_n = (1 - \eta_2)h_n$. Again, by the same arguments as \tilde{h}_n , we obtain

$$\|\nabla \bar{h}_n\|_{L^2(\Omega)} + \frac{1}{\varepsilon_n} \|\bar{h}_n\|_{L^2(\Omega)} \le C\varepsilon_n(\|h_n\|_{H^1(B^c_{\delta/2}(0))} + \|DF_{\varepsilon_n}(0)h_n\|_{L^2(B^c_{\delta/2}(0))}) = o(\varepsilon_n). \tag{4.9}$$

By (4.9), it follows that $\|\bar{h}_n\|_{L^2(\Omega)} = o(\varepsilon_n^2)$ which implies $\|\Delta \bar{h}_n\|_{L^2(\Omega)} = o(1)$. Then by $W^{2,2}$ estimates and $1 - \eta_2 \equiv 1$ in $B^c_{\delta}(0)$, we have $\|h_n\|_{H^2(B^c_{\delta}(0))} = o(1)$ which implies $\|h_n\|_{H^2(B_{\delta}(0))} = 1 + o(1)$.

Set $\hat{h}_n(x) = \eta(\varepsilon_n x) h_n(\varepsilon_n x)$ and $\eta_n(x) = \eta(\varepsilon_n x)$. By a direct computation, \hat{h}_n satisfies

$$\Delta \hat{h}_n + e^{\psi} (1 - 2e^{\psi}) \hat{h}_n = 2\nabla \hat{h}_n \cdot \nabla \eta_n + \hat{h}_n \Delta \eta_n + \varepsilon_n^2 \eta_n [DF_{\varepsilon_n}(0)h_n](\varepsilon_n x)$$

$$+ [e^{\eta_n \psi} (2e^{\eta_n \psi} - 1) - e^{\psi} (2e^{\psi} - 1)] \hat{h}_n.$$

$$(4.10)$$

Set $\hat{\Sigma}_0 = \{\frac{\delta}{\varepsilon_n} \le |x| \le \frac{2\delta}{\varepsilon_n}\}$, $\Sigma_0 = \{\delta \le |x| \le 2\delta\}$. Since the last term in (4.10) vanishes in $\hat{\Sigma}_0^c$, then by (4.9) and our assumption,

$$\begin{aligned} \|\hat{h}_n\|_{H^2(\mathbb{R}^2)} &\leq C(\varepsilon_n \|\nabla \hat{h}_n\|_{L^2(\hat{\Sigma}_0)} + \|\hat{h}_n\|_{L^2(\hat{\Sigma}_0)} + \varepsilon_n \|DF_{\varepsilon_n}(0)h_n\|_{L^2(B_{2\delta}(0))}) \\ &\leq C(\varepsilon_n \|\nabla h_n\|_{L^2(\Sigma_0)} + \varepsilon_n^{-1} \|h_n\|_{L^2(\Sigma_0)} + \varepsilon_n \|DF_{\varepsilon_n}(0)h_n\|_{L^2(B_{2\delta}(0))}) = o(\varepsilon_n). \end{aligned}$$

This contradicts to $||h_n||_{H^2(B_\delta(0))} = 1 + o(1)$. The second part of (II) follows immediately. Since $DF_{\varepsilon}(0)$ is a self-adjoint operator from $H^2(\Omega) \to L^2(\Omega)$, we obtain that DF_{ε} is an isomorphism from $H^2(\Omega)$ to $L^2(\Omega)$.

The estimate for $||DF_{\varepsilon}(v)h - DF_{\varepsilon}(0)h||_{L^{2}(\Omega)}$ follows from

$$DF_{\varepsilon}(v)h - DF_{\varepsilon}(0)h = \frac{1}{\varepsilon^{2}}e^{\eta\psi_{\varepsilon}}(e^{\varepsilon^{3}v} - 1)h - \frac{2}{\varepsilon^{2}}e^{2\eta\psi_{\varepsilon}}(e^{2\varepsilon^{3}v} - 1)h$$

and the embedding of $H^2(\Omega) \hookrightarrow L^{\infty}(\Omega)$.

Proof of Theorem 1.2. We define a functional $G_{\varepsilon}: H^2(\Omega) \to L^2(\Omega)$ by

$$G_{\varepsilon}(v) = v - [DF_{\varepsilon}(0)]^{-1} F_{\varepsilon}(v). \tag{4.11}$$

For any fixed point v_{ε} of G_{ε} in $H^{2}(\Omega)$, $u_{\varepsilon} = \eta \psi_{\varepsilon} + \varepsilon^{3} v_{\varepsilon}$ is a solution of (1.12). It suffices to prove G_{ε} admits a fixed point in $H^{2}(\Omega)$ for $\varepsilon > 0$ small. Set $\mathcal{B} = \{v \in H^{2}(\Omega) | |v|_{H^{2}(\Omega)} \leq 1\}$.

Claim: $G_{\varepsilon}: \mathcal{B} \to \mathcal{B}$ is a well-defined contraction mapping provided $\varepsilon > 0$ is small enough. It follows from Lemma 4.1 that, for $\varepsilon > 0$ small enough,

$$||DG_{\varepsilon}(v)h||_{L^{2}(\Omega)} \leq ||[DF_{\varepsilon}(0)]^{-1}|||(DF_{\varepsilon}(v) - DF_{\varepsilon}(0))h||_{L^{2}(\Omega)} \leq C\varepsilon |h|_{H^{2}(\Omega)}$$

for $v \in \mathcal{B}$. Then by Lemma 4.1, we have

$$||G_{\varepsilon}(0)||_{H^2(\Omega)} \le C||F_{\varepsilon}(0)||_{L^2(\Omega)} \le Ce^{-c/\varepsilon}.$$

For any $v_1, v_2 \in \mathcal{B}$, for $\varepsilon > 0$ small enough, we have

$$||G_{\varepsilon}(v_1)||_{H^2(\Omega)} \leq ||G_{\varepsilon}(0)||_{H^2(\Omega)} + ||G_{\varepsilon}(v_1) - G_{\varepsilon}(0)||_{H^2(\Omega)}$$

$$\leq ||G_{\varepsilon}(0)||_{H^2(\Omega)} + (\sup_{v \in \mathcal{B}} ||DG_{\varepsilon}(v)||) ||v_1||_{H^2(\Omega)} \leq C(e^{-c/\varepsilon} + \varepsilon),$$

and

$$||G_{\varepsilon}(v_1) - G_{\varepsilon}(v_2)||_{H^2(\Omega)} \le (\sup_{v \in \mathcal{B}} ||DG_{\varepsilon}(v)||) ||v_1 - v_2||_{H^2(\Omega)} \le C\varepsilon ||v_1 - v_2||_{H^2(\Omega)}.$$

Hence, if $\varepsilon > 0$ is small enough, $G_{\varepsilon} : \mathcal{B} \to \mathcal{B}$ is a well-defined contraction mapping, which implies G_{ε} has a unique fixed point $v_{\varepsilon} \in \mathcal{B}$. By a direct computation, one can see that $u_{\varepsilon} = \eta \psi_{\varepsilon} + \varepsilon^3 v_{\varepsilon}$ satisfies (1.12). Also from Sobolev embedding $H^2(\Omega) \hookrightarrow L^{\infty}(\Omega)$ and ψ_{ε} decaying exponentially to $0, \forall |x| \geq r, \forall r > 0$, we see u_{ε} is a topological solution.
