APPLICATIONS OF THE 'HAM SANDWICH THEOREM' TO EIGENVALUES OF THE LAPLACIAN

KEI FUNANO

ABSTRACT. We apply Gromov's ham sandwich method to get

- (1) domain monotonicity (up to a multiplicative constant factor);
- (2) reverse domain monotonicity (up to a multiplicative constant factor); and
- (3) universal inequalities

for Neumann eigenvalues of the Laplacian on bounded convex domains in a Euclidean space.

1. Introduction and the statement of main results

Let Ω be a bounded domain in \mathbb{R}^n with piecewise smooth boundary. We denote by $\lambda_0^D(\Omega) \leq \lambda_1^D(\Omega) \leq \cdots \leq \lambda_k^D(\Omega) \leq \cdots$ the Dirichlet eigenvalues of the Laplacian on Ω and by $0 = \lambda_0^N(\Omega) < \lambda_1^N(\Omega) \leq \lambda_2^N(\Omega) \leq \cdots \leq \lambda_k^N(\Omega) \leq \cdots$ the Neumann eigenvalues of the Laplacian on Ω . It is known the following two properties for these eigenvalues:

- (1) (Domain monotonicity for Dirichlet eigenvalues) If $\Omega \subseteq \Omega'$ are two bounded domains, then $\lambda_k^D(\Omega') \leq \lambda_k^D(\Omega)$ for any k.
- (2) (Restricted reverse domain monotonicity for Neumann eigenvalues) If in addition $\Omega' \setminus \Omega$ has measure zero then $\lambda_k^N(\Omega) \leq \lambda_k^N(\Omega')$ for any k.

These two properties are a direct consequence of Courant's minimax principle (see [Cha84]). The following two examples suggest that the domain monotonicity does not hold for Neumann eigenvalues in general.

Example 1.1. Let Ω' be the *n*-dimensional unit cube $[0,1]^n$. Then $\lambda_1^N(\Omega')=1$. However if Ω is a convex domain in $[0,1]^n$ that approximates the segment connecting the origin and the point $(1,1,\cdots,1)$ then $\lambda_1^N(\Omega)\sim 1/n$.

Example 1.2. Let $p \in [1,2]$ and B_p^n be the *n*-dimensional ℓ_p -ball centered at the origin. Suppose that $r_{n,p}$ is the positive number such that $vol(r_{n,p}B_p^n) = 1$ and set $\Omega' := r_{n,p}B_p^n$. Then $r_{n,p} \sim n^{1/p}$ and $\lambda_1^N(\Omega') \geq c$ for some absolute constant c > 0 ([Sod08, Section 4 (2)]). If the segment in Ω' connecting the origin and $(r_{n,p}, 0, 0, \dots, 0)$ is approximated by a convex domain Ω in Ω' then $\lambda_1^N(\Omega) \sim r_{n,p}^{-2} \sim n^{-2/p}$.

In this paper we study the above two properties for Neumann eigenvalues of the Laplacian on convex domains in a Euclidean space. For two real numbers α, β we denote $\alpha \lesssim \beta$ if $\alpha \leq c\beta$ for some absolute constant c > 0.

Date: November 29, 2016.

One of our main theorems is the following:

Theorem 1.3. For any natural number $k \geq 2$ and any two bounded convex domains Ω, Ω' in \mathbb{R}^n with piecewise smooth boundaries such that $\Omega \subset \Omega'$ we have

$$\lambda_k^N(\Omega') \lesssim (n \log k)^2 \lambda_{k-1}^N(\Omega).$$

As a corollary we get the following inner radius estimate:

Corollary 1.4. Let $\Omega \subseteq \mathbb{R}^n$ be a bounded convex domain with piecewise smooth boundary. For any $k \geq 2$ we have

$$\operatorname{inrad}(\Omega) \lesssim \frac{n \log k \sqrt{\lambda_{k-1}^N(B_1)}}{\sqrt{\lambda_k^N(\Omega)}},$$

where B_1 is a unit ball in \mathbb{R}^n .

We also obtain the opposite inequality to Theorem 1.3:

Theorem 1.5. Let Ω, Ω' be two bounded convex domains in \mathbb{R}^n having piecewise smooth boundaries. Assume that Ω is symmetric with respect to the origin (i.e., $\Omega = -\Omega$) and $\Omega \subseteq \Omega'$. Set $v := vol \Omega/vol \Omega' \in [0,1]$. Then for any natural number $k \geq 3$ we have

(1.1)
$$\lambda_{k-2}^{N}(\Omega') \gtrsim \min \left\{ \frac{(\log(1-v))^2}{n^8(\log k)^6}, \frac{1}{n^6(\log k)^4} \right\} \lambda_k^{N}(\Omega).$$

For general (not necessarily symmetric) Ω we have

(1.2)
$$\lambda_{k-2}^{N}(\Omega') \gtrsim \min \left\{ \frac{(\log(1 - 2^{-n}v))^2}{n^8(\log k)^6}, \frac{1}{n^6(\log k)^4} \right\} \lambda_k^{N}(\Omega).$$

As a corollary of Theorems 1.3 and 1.5 we obtain

$$\lambda_k^N(\Omega') \lesssim (n\log k)^2 \lambda_k^N(\Omega) \text{ and } \lambda_k^N(\Omega') \gtrsim \min\Big\{\frac{(\log(1-2^{-n}v))^2}{n^8(\log k)^6}, \frac{1}{n^6(\log k)^4}\Big\} \lambda_k^N(\Omega)$$

for all $k \geq 2$, which corresponds to the above properties (1) and (2) up to multiplicative constant factors. In [Mil09] E. Milman obtained the corresponding inequality for k=1 (see (5.1)). Despite the fact that his inequality is independent of dimension, our two inequalities above involve dimensional terms. However $\log k$ bounds in the two inequalities are nontrivial (Compare with (5.2)). The case where p=1 in Example 1.2 shows that the n^2 order in Theorem 1.3 cannot be improved. Probably there would be a chance to express the multiplicative constant factor in Theorem 1.3 in terms of the volume ratio $v = vol \Omega / vol \Omega'$ to avoid the dependence of dimension (see Question 5.3).

As a special case where $\Omega = \Omega'$ in Theorem 1.3 we obtain the following universal inequalities among Neumann eigenvalues :

(1.3)
$$\lambda_k^N(\Omega) \lesssim (n \log k)^2 \lambda_{k-1}^N(\Omega).$$

By 'universal' we mean it does not depend on the underlying domain Ω itself. Payne, Pólya, and Weinberger studied universal inequalities among Dirichlet eigenvalues ([PPW55,

PPW56]). Since then many universal inequalities for Dirichlet eigenvalues were studied (see [AB07]). For Neumann eigenvalues, Liu ([Liu14]) showed the sharp inequalities

$$\lambda_k^N(\Omega) \lesssim k^2 \lambda_1^N(\Omega)$$

for any bounded convex domain Ω , which improves author's exponential bounds in k in [Fun13]. On the other hand, one can get

(1.5)
$$\lambda_k^N(\Omega) \gtrsim k^{2/n} \lambda_1^N(\Omega)$$

for any bounded convex domain $\Omega \subseteq \mathbb{R}^n$. This inequality follows from the combination of E. Milman's result [Mil09, Remark 2.11] and Cheng-Li's result [CL81] (see [SY94, Chapter III §5]). In fact E. Milman described the Sobolev inequality in terms of $\lambda_1^N(\Omega)$ and Cheng-Li showed lower bounds of $\lambda_k^N(\Omega)$ in terms of the Sobolev constant. The Weyl asymptotic formula says that the inequality (1.5) is sharp. In particular combining (1.4) with (1.5) we can obtain

$$\lambda_k^N(\Omega) \lesssim k^{2-2/n} \lambda_{k-1}^N(\Omega).$$

Comparing with this inequality our inequality (1.3) includes the dimensional term. However the dependence on k is best ever to author's knowledge. It should be mentioned that author's conjecture in [Fun13, Fun16] is $\lambda_k^N(\Omega) \lesssim \lambda_{k-1}^N(\Omega)$ for any bounded convex domain Ω with piecewise smooth boundary.

In the proof of Theorems 1.3 and 1.5 we will use Gromov's method concerning a bisection of finite subsets by the zero set of a finite combination of eigenfunctions. It enables us to get lower bounds for eigenvalues of the Laplacian in terms of Cheeger constants and the maximal multiplicity of a covering of a domain (Proposition 3.1). We will try to find 'nice' convex partition in order to get 'nice' lower bounds for Cheeger constants of pieces of the partition.

2. Preliminaries

2.1. **Separation distance.** Let Ω be a bounded domain in a Euclidean space. For two subsets $A, B \subseteq \Omega$ we set $d_{\Omega}(A, B) := \inf\{|x - y| \mid x \in A, y \in B\}$. We denote by μ the Lebesgue measure on Ω normalized as $\mu(\Omega) = 1$.

Definition 2.1 (Separation distance, [Gro99]). For any $\kappa_0, \kappa_1, \dots, \kappa_k \geq 0$ with $k \geq 1$, we define the (k-)separation distance $\operatorname{Sep}(\Omega; \kappa_0, \kappa_1, \dots, \kappa_k)$ of Ω as the supremum of $\min_{i \neq j} d_{\Omega}(A_i, A_j)$, where A_0, A_1, \dots, A_k are any Borel subsets of Ω satisfying that $\mu(A_i) \geq \kappa_i$ for all $i = 0, 1, \dots, k$.

Theorem 2.2 ([Fun16, Theorem 1]). There exists an absolute constant c > 0 satisfying the following property. Let Ω be a bounded convex domain in a Euclidean space with piecewise smooth boundary and k, l be two natural numbers with $l \leq k$. Then we have

$$\operatorname{Sep}(\Omega; \kappa_0, \cdots, \kappa_l) \leq \frac{c^{k-l+1}}{\sqrt{\lambda_k^N(\Omega)}} \max_{i \neq j} \log \frac{1}{\kappa_i \kappa_j}.$$

The case where k = l = 1 was first proved by Gromov and V. Milman without convexity assumption of domains ([GM83]). Chung, Grigor'yan, and Yau then extended to the case where k = l ([CGY96, CGY97]). To reduce the number l of subsets in Ω in a dimension-free way we need the convexity of Ω (see [Fun16]).

2.2. Cheeger constant and eigenvalues of the Laplacian. For a Borel subset $A \subseteq \Omega$ and r > 0 we denote $U_r(A)$ the r-neighborhood of A in Ω . We define the Minkowski boundary measure of A as

$$\mu_+(A) := \liminf_{r \to 0} \frac{\mu(U_r(A) \setminus A)}{r}.$$

Definition 2.3 (Cheeger constant). For a bounded domain Ω in a Euclidean space we define the *Cheeger constant* of Ω as

$$h(\Omega) := \inf_{A_0, A_1} \max\{\mu_+(A_0)/\mu(A_0), \mu_+(A_1)/\mu(A_1)\},\,$$

where the infimum runs over all non-empty disjoint two Borel subsets A_0, A_1 of Ω .

Let μ be a finite Borel measure on a bounded domain $\Omega \subseteq \mathbb{R}^n$ and $f: \Omega \to \mathbb{R}$ be a Borel measurable function. A real number m_f is called a *median* of f if it satisfies

$$\mu(\lbrace x \in \Omega \mid f(x) \geq m_f \rbrace) \geq \mu(\Omega)/2 \text{ and } \mu(\lbrace x \in \Omega \mid f(x) \leq m_f \rbrace) \geq \mu(\Omega)/2.$$

The following characterization of the Cheeger constant is due to Maz'ya and Federer-Fleming. See [Mil09, Lemma 2.2] for example.

Theorem 2.4 ([FF60], [Maz85]). The Cheeger constant $h(\Omega)$ is the best constant for the following (1,1)-Poincaré inequality:

$$h(\Omega)||f-m_f||_{L^1(\Omega,\mu)} \le |||\nabla f|||_{L^1(\Omega,\mu)} \text{ for any } f \in C^{\infty}(\Omega).$$

Theorem 2.5 (E. Milman [Mil11, Theorem 2.1]). Let Ω be a bounded convex domain in a Euclidean space and assume that Ω satisfies the following concentration inequality for some r > 0 and $\kappa \in (0, 1/2) : \mu(\Omega \setminus U_r(A)) \leq \kappa$ for any Borel subset $A \subseteq \Omega$ such that $\mu(A) \geq 1/2$. Then $h(\Omega) \geq (1 - 2\kappa)/r$.

One can easily check that Theorem 2.5 has the following equivalent interpretation in terms of separation distance.

Proposition 2.6. Let Ω be a convex domain in a Euclidean space. Then for any $\kappa \in (0, 1/2)$ we have

$$\operatorname{Sep}(\Omega; \kappa, 1/2) \ge (1 - 2\kappa)/h(\Omega).$$

In particular we have

$$\operatorname{diam} \Omega \ge 1/h(\Omega).$$

The latter statement can be found in [KLS95, Theorem 5.1] and [Mil09, Theorem 5.12] up to some absolute constant.

Theorem 2.7 ([Krö99, Theorem 1.1], [Che75]). Let Ω be a bounded convex domain in \mathbb{R}^n with piecewise smooth boundary. For any natural number k we have

$$\operatorname{diam}\Omega\lesssim nk/\sqrt{\lambda_k^N(\Omega)}.$$

The Buser-Ledoux inequality asserts that $\sqrt{\lambda_1^N(\Omega)} \gtrsim h(\Omega)$ for any bounded convex domain $\Omega \subseteq \mathbb{R}^n$ with piecewise smooth boundary ([Bus82], [Led04]). As a corollary of Theorem 2.7 we obtain

(2.1)
$$\operatorname{diam} \Omega \lesssim n/h(\Omega).$$

2.3. **Voronoi partition.** Let X be a metric space and $\{x_i\}_{i\in I}$ be a subset of X. For each $i \in I$ we define the *Voronoi cell* C_i associated with the point x_i as

$$C_i := \{ x \in X \mid d(x, x_i) \le d(x, x_j) \text{ for all } j \ne i \}.$$

Note that if X is a bounded convex domain Ω in a Euclidean space then $\{C_i\}_{i\in I}$ is a convex partition of Ω (the boundaries ∂C_i may overlap each other). Observe also that if the balls $\{B(x_i,r)\}_{i\in I}$ of radius r covers Ω then $C_i\subseteq B(x_i,r)$, and thus diam $C_i\subseteq T$ for any $i\in I$.

3. Gromov's ham sandwich method

In this section we explain Gromov's ham sandwich method to estimate eigenvalues of the Laplacian from below. Recall that the classical ham sandwich theorem in algebraic topology asserts that given three finite volume subsets in \mathbb{R}^3 , there is a plane that bisects all these subsets ([Mat03]). In stead of bisecting by a plane we consider bisecting by the zero set of a finite combination of eigenfunctions of the Laplacian in Gromov's ham sandwich method.

Let Ω be a bounded domain in a Euclidean space with piecewise smooth boundary and $\{A_i\}_{i=1}^l$ be a finite covering of Ω ; $\Omega = \bigcup_i A_i$. We denote by $M(\{A_i\})$ the maximal multiplicity of the covering $\{A_i\}$ and by $h(\{A_i\})$ the minimum of the Cheeger constants of A_i , $i = 1, 2, \dots, l$.

Although the following argument is essentially included in [Gro99, Appendix C_{+}] we include the proof for the completeness of this paper.

Proposition 3.1 (Compare with [Gro99, Appendix C_+]). Under the above situation, we have

$$\lambda_l^N(\Omega) \ge \frac{h(\{A_i\})^2}{4M(\{A_i\})^2}.$$

Sketch of Proof. We abbreviate $M := M(\{A_i\})$ and $h := h(\{A_i\})$. Take orthonormal eigenfunctions f_1, f_2, \dots, f_l which correspond to the eigenvalues $\lambda_1^N(\Omega), \lambda_2^N(\Omega), \dots, \lambda_l^N(\Omega)$ respectively.

Step 1. Use the Borsuk-Ulam theorem to get constants c_0, c_1, \dots, c_l such that $f := c_0 + \sum_{i=1}^l c_i f_i$ bisects each $A_1, A_2, \dots A_l$, i.e.,

$$\mu(A_i \cap f^{-1}[0,\infty)) \ge \mu(A_i)/2$$
 and $\mu(A_i \cap f^{-1}(-\infty,0]) \ge \mu(A_i)/2$.

In fact, according to [ST42, Corollary], in order to bisect l subsets by a finite combination of $f_0 \equiv 1, f_1, \dots, f_l$, it suffices to check that f_0, f_1, \dots, f_l are linearly independent modulo sets of measure zero (i.e., whenever $a_0 f_0 + a_1 f_1 + \dots + a_l f_l = 0$ over a Borel subset of positive measure, we have $a_0 = a_1 = \dots = a_l = 0$). This is possible since the zero set of any finite combination of f_0, f_1, \dots, f_l has finite codimension 1 Hausdorff measure ([BHH16, Subsection 1.1.1]).

Step 2. Put $f_+(x) := \max\{f(x), 0\}$ and $f_-(x) := \max\{-f(x), 0\}$. Then we set $g_{\pm} := f_{\pm}^2$. Note that 0 is the median of the restriction of g_{\pm} to each A_i by Step 1. Apply Theorem 2.4 to get $h\|g_{\pm}\|_{L^1(A_i,\mu|_{A_i})} \le \||\nabla g_{\pm}||_{L^1(A_i,\mu|_{A_i})}$ for each i.

Step 3. Use Step 2 to get

$$\int_{\Omega} g_{\pm} d\mu \le \sum_{i=1}^{l} \int_{A_i} g_{\pm} d\mu \le \frac{1}{h} \sum_{A_i} |\nabla g_{\pm}| d\mu \le \frac{M}{h} \int_{\Omega} |\nabla g_{\pm}| d\mu.$$

Recalling that $g_{\pm} = f_{\pm}^2$ and using the Cauchy-Schwarz inequality we have

$$\int_{\Omega} f_{\pm}^2 d\mu \le \frac{4M^2}{h^2} \int_{\Omega} |\nabla f_{\pm}|^2 d\mu.$$

Since the zero set $f^{-1}(0)$ has measure zero we get

$$\int_{\Omega} f^2 d\mu \le \frac{4M^2}{h^2} \int_{\Omega} |\nabla f|^2 d\mu.$$

We therefore obtain $\sum_{i=0}^l c_i^2 \leq (4M^2/h^2) \sum_{i=1}^l c_i^2 \lambda_i^N(\Omega)$ and thus the conclusion of the proposition.

- **Remark 3.2.** 1. In [Gro99] Gromov treated the case where Ω is a closed Riemannian manifold of Ricci curvature $\geq -(n-1)$ and the covering consists of some balls B_i of radius ε in Ω . In stead of considering the (1,1)-Poincaré inequality in terms of Cheeger constants in Step 2 he proved that $\|g\|_{L^1(B_i,\mu|_{B_i})} \leq c(n,\varepsilon) \||\nabla g||_{L^1(\widetilde{B}_i,\mu|_{\widetilde{B}_i})}$, where $g=f^2$, $c(n,\varepsilon)$ is a constant depending only on dimension n and ε , and \widetilde{B}_i is the ball of radius 2ε with the same center of B_i .
- 2. The above proposition is also valid for the case where Ω is a closed Riemannian manifold or a compact Riemannian manifold with boundary. In the latter case we impose the Neumann boundary condition.

As an application of Proposition 3.1 we can obtain estimates of eigenvalues of the Laplacian of closed hyperbolic manifolds due to Buser ([Bus80, Theorems 3.1, 3.12, 3.14]). In fact Buser gave a partition of a closed hyperbolic manifold and lower bound estimates of Cheeger constants of each piece of the partition.

4. Proof of main theorems

Let Ω, Ω' be two bounded convex domains in a Euclidean space. Throughout this section μ is the Lebesgue measure on Ω' normalized as $\mu(\Omega') = 1$.

Proof of Theorem 1.3. We apply Gromov's ham sandwich method (Proposition 3.1) to bound $\lambda_{k-1}^N(\Omega)$ from below in terms of $\lambda_k^N(\Omega')$. To apply the proposition we want to find a finite partition $\{\Omega_i\}_{i=1}^l$ of Ω with $l \leq k-1$ such that the Cheeger constant of each Ω_i can be comparable with $\sqrt{\lambda_k^N(\Omega')}$.

According to Theorem 2.2 we have

(4.1)
$$\operatorname{Sep}\left(\Omega'; \underbrace{\frac{1}{k^n}, \frac{1}{k^n}, \cdots, \frac{1}{k^n}}_{h \text{ times}}\right) \leq \frac{cn \log k}{\sqrt{\lambda_k^N(\Omega')}}$$

for some absolute constant c > 0. We set $R := (cn \log k) / \sqrt{\lambda_k^N(\Omega')}$.

Suppose that Ω' includes k (4R)-separated points x_1, x_2, \dots, x_k . By Theorem 2.7 we have diam $\Omega' \leq c' nk / \sqrt{\lambda_k^N(\Omega')}$ for some absolute constant c' > 0. Applying the Bishop-Gromov inequality we have

$$\mu(B(x_i, R)) \ge (R/\operatorname{diam} \Omega')^n \ge (c \log k)^n/(c'k)^n$$

for each i. If we rechoose c in (4.1) as a sufficiently large absolute constant so that $(c \log k)/c' \ge 1$ we get $\mu(B(x_i, R)) \ge 1/k^n$. Since $B(x_i, R)$'s are 2R-separated this contradicts to (4.1).

Let y_1, y_2, \dots, y_l be maximal 4R-separated points in Ω' , where $l \leq k-1$. Since $\Omega' \subseteq \bigcup_{i=1}^l B(y_i, 4R)$ if $\{\Omega'_i\}_{i=1}^l$ is the Voronoi partition associated with $\{y_i\}$ then we have diam $\Omega'_i \leq 8R$. Setting $\Omega_i := \Omega'_i \cap \Omega$ we get $\Omega = \bigcup_{i=1}^l \Omega_i$ and diam $\Omega_i \leq 8R$. Since each Ω_i is convex, Proposition 2.6 gives $h(\Omega_i) \geq 1/(8R)$. Applying Proposition 3.1 to the covering $\{\Omega_i\}$ we obtain

$$\lambda_{k-1}^{N}(\Omega) \ge \lambda_{l}^{N}(\Omega) \ge 1/\{4(8R)^{2}\} \ge \lambda_{k}^{N}(\Omega')/(16cn\log k)^{2},$$

which yields the conclusion of the theorem. This completes the proof.

In order to prove Theorem 1.5 we prepare several lemmas.

Lemma 4.1 ([Mil09, Lemma 5.2]). Let Ω, Ω' be two bounded convex domains in \mathbb{R}^n such that $\Omega \subseteq \Omega'$. Assume that $vol \Omega \geq v \ vol \Omega'$. Then we have $h(\Omega') \geq v^2 h(\Omega)$.

Lemma 4.2. Let Ω, Ω' be two bounded convex domains in \mathbb{R}^n having piecewise smooth boundaries such that $\Omega \subseteq \Omega'$. Assume that $\operatorname{vol} \Omega \geq (1 - k^{-n}) \operatorname{vol} \Omega'$ for some natural number $k \geq 2$. Then we have

$$(n^2 \log k)^2 \lambda_{k-1}^N(\Omega') \gtrsim \lambda_k^N(\Omega).$$

Proof. Due to Theorem 2.2 we have

(4.2)
$$\operatorname{Sep}\left(\Omega; \underbrace{\frac{1}{k^n}, \frac{1}{k^n}, \cdots, \frac{1}{k^n}}_{k \text{ times}}\right) \leq \frac{cn \log k}{\sqrt{\lambda_k^N(\Omega)}}.$$

We set $R := (cn^2 \log k)/\sqrt{\lambda_k^N(\Omega)}$. As in the proof of Theorem 1.3 we have maximal 4R-separated points $x_1, x_2, \dots, x_l \in \Omega$ such that $l \leq k-1$. We get $\Omega \subseteq \bigcup_{i=1}^l B(x_i, 4R)$.

Claim 4.3.
$$U_R(\Omega) = \Omega'$$
.

Let us admit the above claim for a while. The above claim yields $\Omega' \subseteq \bigcup_{i=1}^l B(x_i, 5R)$. Let $\{\Omega'_i\}_{i=1}^l$ be the Voronoi partition associated with $\{x_i\}$ then we have diam $\Omega'_i \leq 10R$. Proposition 2.6 gives $h(\Omega'_i) \geq 1/(10R)$. According to Proposition 3.1 we obtain

$$\lambda_{k-1}^{N}(\Omega') \ge 1/(20R)^2 = \lambda_k^{N}(\Omega)/(20cn^2 \log k)^2,$$

which implies the lemma.

Suppose that $U_R(\Omega) \neq \Omega'$. There exists $x \in \partial \Omega'$ such that $B(x,R) \cap \Omega = \emptyset$. Lemma 4.1 together with Proposition 2.6 and (2.1) show that

$$\operatorname{diam} \Omega' \lesssim n/h(\Omega') \lesssim n/h(\Omega) \leq n \operatorname{diam} \Omega,$$

which gives the existence of an absolute constant $c_1 > 0$ such that diam $\Omega' \leq c_1 n \operatorname{diam} \Omega$. The Bishop-Gromov inequality yields

$$\mu(B(x,R)) \ge (R/\operatorname{diam} \Omega')^n \ge R^n/(c_1 n \operatorname{diam} \Omega)^n.$$

Since diam $\Omega \leq c_2 nk/\sqrt{\lambda_k^N(\Omega)}$ for some absolute constant $c_2 > 0$ (Theorem 2.7) we have

$$\mu(B(x,R)) \ge (c \log k)^n / (c_1 c_2 k)^n > 1/k^n,$$

provided that c is large enough absolute constant such that $(c \log k)/(c_1c_2) > 1$. We thereby obtain

$$\mu(B(x,R) \cup \Omega) = \mu(B(x,R)) + \mu(\Omega) > 1/k^n + (1 - 1/k^n) = 1,$$

which is a contradiction.

In order to adapt to the hypothesis of Lemma 4.2 we use the following improvement of Borell's lemma.

Theorem 4.4 ([Gué99, Section 1 Remark]). Let Ω, Ω' be two bounded convex domains such that $\Omega \subseteq \Omega'$. Assume that Ω is symmetric. Then for any $r \geq 1$ we have

$$\mu(\Omega' \setminus r\Omega) \le (1 - \mu(\Omega))^{\frac{r+1}{2}},$$

where $r\Omega := \{rx \mid x \in \Omega\}.$

Proof of Theorem 1.5. We first consider the case where Ω is symmetric. According to Theorem 4.4 setting

$$r := 2\max\left\{\frac{n\log k}{-\log(1-v)}, 1\right\}$$

we have $\mu(\Omega' \setminus r\Omega) < 1/k^n$. Take a bounded convex domain $\widetilde{\Omega} \subseteq r\Omega \cap \Omega'$ with piecewise smooth boundary such that $\Omega \subseteq \widetilde{\Omega}$ and $\mu(\Omega' \setminus \widetilde{\Omega}) < 1/k^n$. Since $\widetilde{\Omega} \subseteq r\Omega$ Theorem 1.3 implies

$$(4.3) (nr \log k)^2 \lambda_{k-1}^N(\widetilde{\Omega}) \gtrsim r^2 \lambda_k^N(r\Omega) = \lambda_k^N(\Omega).$$

Using Lemma 4.2 we also obtain

$$(4.4) (n^2 \log k)^2 \lambda_{k-2}^N(\Omega') \gtrsim \lambda_{k-1}^N(\widetilde{\Omega}).$$

Combining the above two inequalities (4.3) and (4.4) we obtain (1.1).

For general (not necessarily symmetric) Ω , there exists a choice of a center (we may assume here that the center is the origin without loss of generality) such that $vol(\Omega \cap -\Omega) \geq 2^{-n} \, vol\,\Omega$ ([Ste56, Corollary]). By virtue of Theorem 4.4 setting

$$r := 2 \max \left\{ \frac{n \log k}{-\log(1 - 2^{-n}v)}, 1 \right\}$$

we get $\mu(\Omega' \setminus r\Omega) \leq \mu(\Omega' \setminus r(\Omega \cap -\Omega)) < 1/k^n$. Thus applying the same proof of the symmetric case we obtain (1.2). This completes the proof.

5. Questions

In this section we raise several questions which concern this paper.

Question 5.1. Let Ω be a bounded convex domain in \mathbb{R}^n with piecewise smooth boundary. Then for any natural number k and $\kappa_0, \kappa_1, \dots, \kappa_k > 0$ can we get

$$\operatorname{Sep}(\Omega; \kappa_0, \kappa_1, \cdots, \kappa_k) \lesssim \frac{1}{(\log k) \sqrt{\lambda_k^N(\Omega)}} \max_{i \neq j} \log \frac{1}{\kappa_i \kappa_j}$$
?

We can subtract $\log k$ terms in Theorems 1.3 and 1.5 once we get an affirmative answer to Question 5.1 since [Fun16, Theorem 3.4] gives

$$\operatorname{Sep}(\Omega; \kappa_0, \kappa_1, \cdots, \kappa_l) \le \frac{c^{k-l+1}}{(\log k) \sqrt{\lambda_k^N(\Omega)}} \max_{i \ne j} \log \frac{1}{\kappa_1 \kappa_j}$$

for any two natural numbers $l \leq k$ and any $\kappa_0, \kappa_1, \dots, \kappa_l > 0$, where c > 0 is an absolute constant.

Question 5.2. Let Ω be a bounded convex domain in \mathbb{R}^n with piecewise smooth boundary and assume that Ω satisfies the following (k-1)-separation inequality for some k:

$$\operatorname{Sep}((\Omega, \mu); \kappa_0, \kappa_1, \cdots, \kappa_{k-1}) \leq \frac{1}{D} \max_{i \neq j} \log \frac{1}{\kappa_i \kappa_j} \quad (\forall \kappa_0, \kappa_1, \cdots, \kappa_{k-1} > 0).$$

Then do there exist an absolute constant c > 0 and a convex partition $\Omega = \bigcup_{i=1}^{l} \Omega_i$ with $l \leq k-1$ such that

$$\mu(\Omega_i) \ge \frac{1}{ck} \text{ and } \operatorname{Sep}((\Omega_i, \mu|_{\Omega_i}); \kappa, \kappa) \le \frac{c}{D} \log \frac{1}{\kappa}$$

for any κ ?

KEI FUNANO

An affirmative answer to Question 5.2 implies the universal inequality $\lambda_k^N(\Omega) \lesssim (\log k)^2 \lambda_{k-1}^N(\Omega)$ via Theorem 2.5 and Proposition 3.1. If both Questions 5.1 and 5.2 is affirmative then we can obtain $\lambda_k^N(\Omega) \lesssim \lambda_{k-1}^N(\Omega)$.

Question 5.3. Let Ω, Ω' be two bounded convex domains with piecewise smooth boundaries such that $\Omega \subseteq \Omega'$. Set $v := vol \Omega/vol \Omega' \in [0,1]$. Can we prove $\lambda_k^N(\Omega) \leq f_1(v)g_1(\log k)\lambda_k^N(\Omega')$ and $\lambda_k(\Omega') \leq f_2(v)g_2(\log k)\lambda_k^N(\Omega)$, where f_1 and f_2 are any functions and g_1 and g_2 are some rational functions?

When k = 1 E. Milman obtained

(5.1)
$$\lambda_1^N(\Omega') \ge v^4 \lambda_1^N(\Omega) \text{ and } \lambda_1^N(\Omega) \gtrsim (1/\log(1+1/v))^2 \lambda_1^N(\Omega')$$

(see [Mil09, Lemmas 5.1, 5.2]). Combining this inequality with (1.4) and (1.5) we can get

$$(5.2) \lambda_k^N(\Omega') \gtrsim v^4 k^{\frac{2}{n}-2} \lambda_k^N(\Omega) \text{ and } \lambda_k^N(\Omega) \gtrsim (k^{\frac{1}{n}-1}/\log(1+1/v))^2 \lambda_k^N(\Omega'),$$

but this does not imply the answer to Question 5.3.

Acknowledgments. The author would like to express his appreciation to Prof. Larry Guth for suggesting Gromov's ham sandwich method and many stimulating discussion. The author also would like to thank to Prof. Emanuel Milman for useful comments, especially pointing out Examples 1.1 and 1.2, and to Prof. Alexander Grigor'yan for corrections of the 1st version of this paper and useful comments. The author is grateful to Prof. Boris Hanin, Prof. Ryokichi Tanaka, and Dr. Gabriel Pallier for useful comments and anonymous referees for their helpful suggestions. This work was done during the author's stay in MIT. The author thanks for its hospitality and stimulating research environment.
